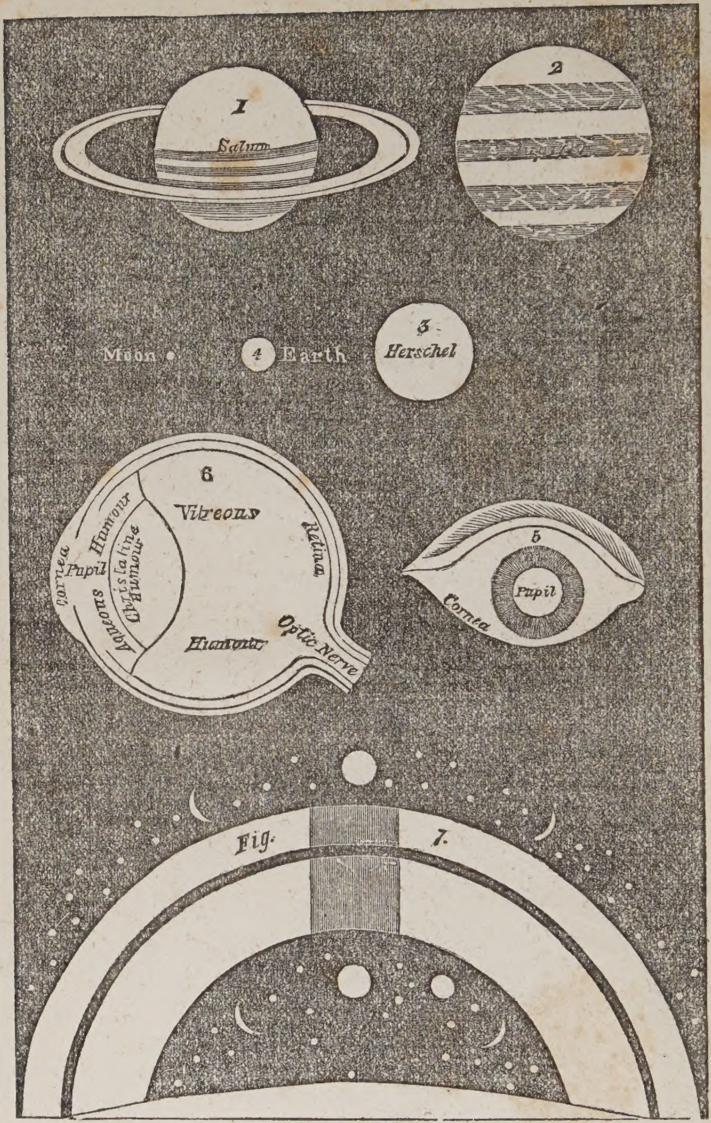
Class. No. R081 Book No. D547
Acc. No. 2471 Date 4-15-47

FOR REFERENCE ONLY

Rob. W. Putnam.

Presented to
J. B. Fox,
1893



The above engraving represents a view of the rings and moons of Saturn, as they would appear to a spectator from the surface of Saturn, at a point about 15 or 20 degrees north of its equator. The shadow of the body of the planet appears about the middle of the rings at midnight. At sunset this shadow will appear on the eastern side of the rings, and will appear to move gradually onward from east to west until sunrise, when it will disappear from the western side of the rings. See pages 86, 87.

THE

COMPLETE WORKS

OF

THOMAS DICK, LL. D.:

ELEVEN VOLUMES IN TWO.

VOLUME ONE, CONTAINING:

I. AN ESSAY ON THE IMPROVEMENT OF SOCIETY.
II. THE PHILOSOPHY OF A FUTURE STATE.
III THE PHILOSOPHY OF RELIGION.
IV. THE MENTAL ILLUMINATION AND MORAL IMPROVEMENT OF MANKIND.
V. AN ESSAY ON THE SIN AND EVILS OF COVETOUSNESS.

VOLUME TWO, CONTAINING:

I. THE CHRISTIAN PHILOSOPHER; OR, SCIENCE AND RELIGION.
II. CELESTIAL SCENERY—ILLUSTRATED.
III SIDEREAL HEAVENS, PLANETS, ETC.
IV. THE PRACTICAL ASTRONOMER.
V. THE SOLAR SYSTEM—ITS WONDERS.
VI. THE ATMOSPHERE, AND ATMOSPHERICAL PHENOMENA.

ILLUSTRATED WITH ENGRAVINGS.
AND A PORTRAIT OF THE AUTHOR.

VOL. II.

THE

CHRISTIAN PHILOSOPHER;

OR,

THE CONNECTION OF SCIENCE AND PHILOSOPHY WITH RELIGION.

FROM THE LAST LONDON EDITION.

2471

PREFACE.

The following pages were written under the impression, that the visible manifestations of the attributes of the Deity are too frequently overlooked by Christians in their views of the great objects of Religion, and in the worship they offer to the Father of their spirits; and are intended to show, that the teachers of Religion, in imparting instruction either to the old or to the young, ought to embrace a wider range of illustration, in reference to divine subjects, than that to which they are usually confined.

Throughout the whole of the discussions contained in this work, the Author has pursued his own train of thought; and in so doing, he trusts that he has been enabled to render some of his illustrations more interesting to the young and untutored mind, than if he had adhered rigidly to the sentiments of others, and to the technical language of science. The sketches of the different sciences are not mere extracts or compilations, but are, for the most part, original composition—in which it has been his main object to embody as many facts as his limits would permit—in order to excite the inquiring mind to further investigations into the different departments of physical science.

It is presumed, that no Christian reader will for once imagine, that the views illustrated in this work are intended to be *substituted* in place of the peculiar revelations of the Bible. The object of the volume is to illustrate the harmony which subsists between the system of Nature and the system of Revelation; and to show, that the manifestations of God in the material universe ought to be blended with our views of the facts and doctrines recorded in the volume of Inspiration.

It is taken for granted, throughout the whole range of the following illustrations, that the Scriptures contain a Revelation from Heaven; and under a firm belief of this important truth, the Author has embellished his work with frequent quotations from the energetic and sublime language of this Sacred book. It would, therefore, be unfair in any critic, who entertains doubts on this point, to find fault with such quotations, or with the allusions to Bible-phraseology which occur, unless they can be shown to be introduced without judgment or discrimination.

In consequence of the progress of the Arts and Sciences since the Last Edition of the following work was published—the Author has deemed it expedient to make a thorough revision of the whole, so as to embrace the latest improvements and discoveries in the different departments to which its diversified subjects refer. He has accordingly carefully revised every portion of the volume, and made very considerable additions to its several departments. The article GEOLOGY has been almost entirely re-written, and enlarged to more than double its former extent. The article

GEOGRAPHY has been enlarged by an addition of several pages. The articles ASTRONOMY, NATURAL PHILOSOPHY, CHEMISTRY, PHYSIOLOGY, HISTORY, PRINTING, MARINER'S COMPASS, TELESCOPE, AIR BALLOONS, STEAM NAVIGATION, etc., have likewise been considerably enlarged. To the former subjects are now added comprehensive sketches of the following recently-discovered departments of Science and Art—The DAGUERREOTYPE, ELECTROTYPE, ELECTRO-MAGNETISM, ELECTRIC TELEGRAPHS, RAILROADS, etc., beside a variety of paragraphs inserted in numerous places throughout the body of the work. Between twenty and thirty additional engravings have been inserted, and to the whole is now added a copious INDEX. These additions amount to more than thirty pages.

This work, in its original form, has had an extensive sale, not only in Great Britain, but also in the United States of America. It is therefore hoped that the improvements and additions which have now been made will render it still more acceptable to the public.

BROUGHTY FERRY, NEAR DUNDEE

CONTENTS.

INTRODUCTION.

Page

Necessity of revelation. Folly of discarding the science of nature from religion. Beneficial effects which flow from the study of the works of God.................................

CHAPTER I.

OF THE NATURAL ATTRIBUTES OF THE DEITY.

SECTION I.

ON THE RELATION OF THE NATURAL ATTRIBUTES OF THE DEITY TO RELIGION.

The Christian Religion founded on the natural attributes of God. His power as interesting a subject as his mercy, illustrated in two instances. Evils which arise from imperfect conceptions of Divine power. Defects in religious instructions on this subject. Sources of illustration.. 14

SECTION II.

ILLUSTRATIONS OF THE OMNIPOTENCE OF THE DEITY.

The material world exhibits a more striking display of this perfection than the supernatural facts recorded in Scripture. *Immense quantity of matter in the universe.* Mode of acquiring the most comprehensive conception of the bulk of the earth—its variety of scenery—its mass of solid matter. Magnitude of the bodies which compose the solar system. Magnitude and number of the stars. Procedure of the mind in acquiring the most impressive conceptions of such august objects. Reflections. *Rapid motions of the celestial bodies.* How we acquire the ideas of relative velocities. Weight of the earth. Immense physical forces. Grandeur of the motion of Saturn. Immense number of bodies impelled through the heavens. Reflections. *Immense spaces which surround the heavenly bodies.* Reflections. Popular illustration of the motions of the earth and heavens. Extract from Dr. Ridgeley, with remarks. Universe intended to *adumbrate* the attributes of God, and to make a sublime impression on created beings. Similar trains of thought suggested in the Scriptures. *Moral effects* of such contemplations. *Humility*—folly of pride—low rank of man in the scale of being. *Reverence* and *veneration.* Reason why mankind feel so little veneration of God—how it may be increased. The Deity unsearchable. *Hope* and *confidence* in the prospect of futurity—resurrection. Scenes of eternity.. 16

SECTION III.

ON THE WISDOM AND INTELLIGENCE OF THE DEITY.

Wisdom defined—displayed in the structure of the solar system. Distance of the sun. Rotation of the planets—principal reason why such a motion exists. Wisdom displayed in other systems. Minute displays of this attribute cannot be traced in the heavens. Wisdom as displayed in the constitution of our globe—adjustment of its solid parts to the necessities of the beings which inhabit it. *Mountains*—their uses exist in other worlds. Diversity of color—argument for a plurality of worlds—general color which prevails in the scene of nature. *Water*—its use in the system of nature—its composition—evaporation—motion of the liquid element—its beneficial effects. The *atmosphere*—its weight and pressure—its component parts—its various properties—necessary to animal life, flame, sound, twilight—wisdom displayed in its constitution. Expansion of water in the act of freezing.......................... 27

VARIETY OF NATURE.

Vegetables—their number and variety. Animals—variety in their organization. Eyes of insects—their exquisite mechanism. Subterraneous regions. Atmosphere. The variety of nature affords a faint idea of the *infinity* of the Creator—illustrated in the number of animal parts and functions. Reflection. Variety of the foundation of our judgments. Beauty and sublimity of nature. Primeval state of our globe. Other worlds........................ 33

MECHANISM OF ANIMATED BEINGS. STRUCTURE OF THE HUMAN EYE.

Its coats, humors, muscles, orbit, and motions. Wisdom displayed in its construction. *Light*—its velocity, minuteness, colors, and adaptation to the eye. Manner in which vision is performed—explained by a figure, and an experiment—illustrated by the view from Salisbury Crags. Multitude of rays which flow from every object—smallness of the image on the retina, illustrated by calculation—what proportion of the solar light falls on our globe. Reflections. Mechanism for viewing near and distant objects—contraction and dilatation of the pupil—distance at which we see distinctly. Summary view of adaptations in the structure of the eye. Eyes of superior intelligences. Visual organs of the inferior animals. *Mechanism of the bones* illustrated—exemplified in the joints of the fingers, the wrist, and the movements of which the head is susceptible. Illustration of the horizontal motion of the wrist, and the utility of the human hand, with figures. Moral reflections on the impropriety of overlooking the Divine wisdom in the system of nature.............................. 37

SECTION IV.

ON THE GOODNESS OR BENEVOLENCE OF THE DEITY.

Benevolence of God in relation to *Man*. What would be the constitution of the world were its Creator a malevolent Being. Benevolence displayed to man, though a depraved intelligence. *Mercy* displayed in the system of nature. Benevolence as displayed toward the lower animals. Extract from Dr. Paley. General reflections.. 46

CHAPTER II.

A CURSORY VIEW OF SOME OF THE SCIENCES WHICH ARE RELATED TO RELIGION AND CHRISTIAN THEOLOGY.

Introduction—extensive range of theology. Bad effects of setting Religion in opposition to Science. Harmony of the operations of God in nature and revelation...................... 49

NATURAL HISTORY.

Its extensive range. Outline of its principal objects—on the surface and in the interior recesses of the earth—in the atmosphere—the vegetable, mineral, and animal kingdoms—and in the region of the heavens. Description of the Banian tree. Reflections. Monkey bread tree. Splendor and felicity of insect life. Invisible worlds. Infinity of the universe. *Religious tendency of this science*—it affords a manifestation of the Deity, and expands our conceptions of his operations—ennobles the human mind—recommended by the sacred writers.......... 50

GEOGRAPHY.

Its object. Figure of the earth—proofs of its spherical form. Relation which the discovery of the figure of the earth bears to the plan of Providence. How the diameter of the earth enables us to calculate the distances of the heavenly bodies—illustrated with figures. Magnitude and natural divisions of the earth—general features of its surface. *Mountains*—their general ranges, and the sublime scenes they exhibit. The *Ocean*—its extent, depth, bottom, and motions. *Rivers*—their number, size, and the quantity of water they pour into the ocean. How they are supplied—their use in the system of nature. *Artificial* division of the earth. *Europe*—description of its extent, commerce, population, &c. *Asia*—its extent, population, and productions. *Africa*—its divisions, extent, and characteristics. *America*—its dimensions, lakes, rivers, &c. *United States*—their extent, population, literature, &c. *Australasia*—the countries it comprehends. New South Wales, South Australia, &c. Van Dieman's Land, New Zealand, New Guinea, New Britain, &c. Polynesian Islands. *Tahiti*—its characteristics, and the moral improvement of its inhabitants. Sandwich Islands—their improvement. Friendly Islands, Navigator's, Marquesas, New Hebrides. Murder of Williams the Missionary. Number and variety of the earth's inhabitants—number which has existed since the Creation—number at the Resurrection, and the space they would occupy—number which the earth would contain—strictures on Malthus. *Utility of the study of geography to religion*—to directors of Missionary Societies—to private Christians. Works on the subject of Christian Missions characterized and recommended—grandeur of its physical objects—utility of its moral facts.. 56

GEOLOGY.

Its object and connection with religion—an interesting subject of inquiry. Materials which compose the crust of our globe. *Primary* rocks—their constituent materials and general aspect. *Transition* rocks—their formation, &c. *Secondary* rocks, coal formations, &c. *Upper* secondary rocks, and their organic remains. Tertiary rocks—their deposits and fossil shells. *Diluvial* deposits. *Alluvial*, and the deltas formed by. *Volcanic* rocks, trap, basalt, Fingal's cave, Giant's causeway, &c. General remarks on organic remains. Various geological phenomena. Periods of organic remains. Description of the Mammoth, Megatherium, &c., with a figure. Conclusions deduced from the facts of geology—their accordance with Sacred History. Genesis, i, 1, explained. High antiquity of the earth not inconsistent with Scripture. Discoveries of astronomy illustrative of geology. Progression a characteristic of the Divine plans, both in the physical and moral world. Date of the present system of our globe. Genesis, i, 2, illustrated. Sublime objects which this science exhibits.................... 68

ASTRONOMY.

Its sublime objects. Apparent motions of the sun—of the moon. Eclipses of the sun and moon. Apparent motion of the starry heavens. Position of the Pole-star and Ursa Major, described and represented. Stars and planets seen in the day-time, and with what powers of the telescope they may be distinguished. Apparent revolution of the celestial vault indicates Almighty power. Stars never shift their relative positions. *Solar system.* The *Sun*—his size and probable destination illustrated—his spots and atmosphere—different kinds of rays emitted from his body—his distance illustrated. *Mercury*—his size, rotation, quantity of light and heat, &c. Proportion of caloric on the different planets. *Venus*—her size, phases, mountains, transits, and general phenomena. Original observations on, and mode by which her diurnal rotation may be determined. *Earth*—proofs of its annual and diurnal motions. The *Moon*—description of her majestic mountain scenery, luminous spots, celestial appearances, illuminating power, superficial contents, &c. *Mars*—his distance, atmosphere, luminous zone, &c. *New planets*—Ceres, Pallas, Juno, and Vesta—their anomalies, singularities, and probable origin. Meteoric stones. *Jupiter*—his bulk, rotation, belts, and the appearances of his moons. Telescopic view of his belts and satellites. *Saturn*—his figure, belts, moons, and quantity of light. His *Rings*—their dimensions, motion, and phenomena—illustrated by a figure. Supposed division of his exterior ring. Splendor of the firmament, as viewed from this planet (*see the Frontispiece*). *Herschel*—his distance, size, and quantity of light. *Comets*—their tails, velocity, orbits, size and number. Encke's, Gambart's, and Halley's comets. Motion of the solar system in absolute space—its destination. Plurality of worlds intimated in Scripture. *The fixed stars*—their distance illustrated—arrangement—changes. Moral reflections. Parallax and distance of 61 Cygni. Figure and description of Orion. *Relation of Astronomy to Religion*—moral effects which its objects have a tendency to produce—criminality of overlooking the works of God, &c............. 78

NATURAL PHILOSOPHY.

Its object and different departments. *Mechanics*—subjects it embraces, and its importance to the improvement of mankind. *Hydrostatics*—its leading principles and uses, illustrated by figures. *Pneumatics*—its principles, and the experiments by which they are illustrated. *Acoustics*—various facts in relation to sound. *Optics*—leading facts and principles of this science. Burning glasses, &c. The *Daguerreotype*—description of its nature, processes, and effects. *Electricity*—its nature, phenomena, effects, and agency in the system of nature. *Electrotype*—its invention and practical applications. *Galvanism*—its singular effects on metals, &c., and on the animal system—applied to the blasting of rocks—various facts which it explains. *Magnetism*—its various phenomena and effects. *Electro-Magnetism*—its phenomena and effects. Relation of Natural Philosophy to Religion—its inventions meliorate the condition of mankind—illustrated in the case of the electric fluid—it undermines the influence of superstition—unfolds the incessant agency of God—indifference to this subject unreasonable.. 92

CHEMISTRY.

Its objects, and present dignified station. General forms of matter—simple and compound substances. *Caloric*—its sources and properties. *Oxygen*—its properties and combinations. *Nitrous Oxide*—its singular effects. *Nitrogen*—its effects on flame and animal life. *Hydrogen*—its properties and uses. *Carbon*—its nature, combinations, and antiseptic properties. *Chlorine*—its properties. *Iodine*—its discovery. *Sulphur*—its origin, combinations, and properties. *Phosphorus*—history of its discovery—how prepared—curious experiments with this substance—phosphoric phenomena in the system of nature—connection of this science with religion—it displays the wisdom and benevolence of God, and the mode of his present and future operations—improves the condition of man, and carries forward our views to a more glorious and auspicious era.. 103

ANATOMY AND PHYSIOLOGY.

Their general object. Human body—its different parts and divisions. *Bones*—their number, form, and positions. *Muscles*—their nature, use, and extraordinary strength. *Heart and blood-vessels,* and the circulation of the blood. *Respiration*—curious structure of the lungs. *Digestion. Perspiration. Sensation,* and the system of nerves. Summary. Moral reflections—this branch of study teaches us our dependence on a Superior Power, and excites to gratitude.......... 108

HISTORY, ANCIENT AND MODERN.

Its objects, advantages, and connection with religion. Connection of the sciences and of the Divine dispensations with each other. Concluding remarks.......... 112

CHAPTER III.

THE RELATION WHICH THE INVENTIONS OF ART BEAR TO THE OBJECTS OF RELIGION.

Art of Printing—its origin, and beneficial effects—stereotype and steam printing.......... 114

Art of Navigation—mariner's compass—its discovery and use.......... 115

The *Telescope*—its invention, and the discoveries made by it—serves instead of a celestial vehicle. Magnifying powers of Sir W. Herschel's telescopes. Earl of Rosse's speculum.... 117

The *Microscope*, and views it exhibits of the wisdom of God.......... 118

Steam Navigation—its utility in promoting the intercourse of mankind—voyages across the Atlantic—its relation to the objects of religion.......... 118

Air Balloons—utility of—when arrived at perfection—proposed improvement in. History of their invention. Lunardi's ascent. The Parachute. Late improvements in, &c.......... 119

Acoustic Tunnels. Experiments on the conveyance of sound. M. Biot's remarkable experiments—Don Gautier's experiment and suggestion. Conclusions in reference to the extensive conveyance of sound.......... 122

Electric Telegraphs—their nature and applications.......... 123

Railways—their history, number, utility, and arrangements.......... 124

Practical remarks—utility of the arts in relation to the Millennial era.......... 127

CHAPTER IV.

SCRIPTURAL FACTS ILLUSTRATED FROM THE SYSTEM OF NATURE.

I. Science may frequently serve as a guide to the true interpretation of Scripture. *Canon or rule for Scripture interpretation*—illustrated.......... 128

II. The *Depravity of Man,* illustrated, from a consideration of the state of the interior strata of the earth. Volcanoes, and the terrible ravages they produce. Earthquakes, and their dreadful effects. Thunder-storms, tempests, and hurricanes. General reflections on this subject.......... 129

III. The *Resurrection* illustrated. Transformations of insects. Indestructibility of matter—conclusions from it.......... 133

IV *General Conflagration.* Concluding reflections. *Topics omitted in this volume*.......... 134

CHAPTER V.

BENEFICIAL EFFECTS WHICH WOULD RESULT FROM CONNECTING SCIENCE WITH RELIGION.

I. The *variety* of topics would allure the attention of intelligent minds to religious subjects. Principle of novelty intended by the Creator to be gratified—illustrated in the variety which appears in the earth, the heavens, and the Volume of Revelation.......... 136

II. Science enables us to take an *extensive survey of the empire of God*—illustrates many sublime passages of the Bible—qualifies us for complying with several Divine injunctions—danger of selfishness and indifference in this respect. Our conceptions of God depend on our views of the extent of his dominions.......... 136

III. Science enlarges our views of the *operations of Providence*, in relation to the past and present scenes of the world. The economy of the inferior animals. The *physical* and *moral* economy of the celestial worlds.......... 141

IV. Science, blended with religion, would produce a general expansion of mind, and liberality of views, in reference to the opinions and actions of men, and to the works and the ways of God, illustrated at large.......... 144

V. It would induce a spirit of *piety*, and profound humility. Sources of piety, illustrated by example. Humility—illustrated by the examples of Mr. Boyle, of Sir Isaac Newton, and of superior intelligences. General conclusions.......... 146

APPENDIX.

Note I. Illustration of the rate of motion in the heavenly bodies, on the supposition that the earth is at rest, 148.—Note II. Experimental illustrations of the pressure and compressibility of the atmosphere, the diving-bell, &c., 149.—Note III. On the ideas of magnitude, motion, and duration, as expressed by numbers, 150.—Note IV. On the means by which it may probably be ascertained whether the moon be a habitable world, 150.—Note V. Remarks on the late pretended discovery of a lunar fortification, 151.—Note VI. On a plurality of worlds, 151.—Note VII. The Daguerreotype, 152.—Note VIII. Electro-Magnetic Machines, 152.—Note IX. On the first inventor of Printing, 153.—Note X. On Telescopes, with a brief notice of a *New Reflecting Telescope,* constructed by the author, 153.—Note XI. On Steam Navigation, &c., 154.—Note XII. Strictures on a certain sentiment respecting the work of human redemption, 156.—Note XIII. Extract from Dr. Dwight's Theology, 157.—Note XIV. List of popular works on the different sciences treated of in this volume, with occasional remarks, 157.

THE

CHRISTIAN PHILOSOPHER.

INTRODUCTION.

On the subject of Religion, mankind have, in all ages, been prone to run into extremes. While some have been disposed to attach too much importance to the mere exertions of the human intellect, and to imagine that man, by the light of unassisted reason, is able to explore the path of true wisdom and happiness,—the greater part of religionists, on the other hand, have been disposed to treat scientific knowledge, in its relation to religion, with a degree of indifference bordering upon contempt. Both these dispositions are equally foolish and preposterous. For he who exalts human reason, as the only sure guide to wisdom and felicity, forgets that man, in his present state, is a *depraved* intelligence, and consequently liable to err; and that all those who have been left solely to its dictates, have uniformly failed in attaining these desirable objects. During a period of more than 5800 years, the greater part of the human race have been left solely to the guidance of their rational powers, in order to grope their way to the Temple of Knowledge, and the Portals of Immortality; but what has been the result of all their anxious researches? Instead of acquiring correct notions of the Great Author of their existence, and of the nature of that homage which is due to his perfections, "they have become vain in their imaginations, and their foolish hearts have been darkened. Professing themselves to be wise, they have become fools; and have changed the glory of the Incorruptible God into an image made like to corruptible man, and to four-footed beasts, and creeping things." Instead of acquiring correct views of the principles of moral action, and conducting themselves according to the eternal rules of rectitude, they have displayed the operation of the most diabolical passions, indulged in continual warfare, and desolated the earth with rapine and horrid carnage; so that the history of the world presents to our view little more than a series of revolting details of the depravity of our species, and of the wrongs which one tribe of human beings has willfully inflicted upon another.

This has been the case, not only among a few uncultivated hordes on the coast of Africa, in the plains of Tartary, and the wilds of America, but even among those nations which stood highest in the ranks of civilization and of science.—The ancient Greeks and Romans, who boasted of their attainments in philosophy, and their progress in the arts, entertained the most foolish, contradictory, and unworthy notions of the Object of Divine worship, of the requirements of religion, and of the eternal destiny of man. They adored a host of divinities characterized by impiety, fraud, injustice, falsehood, lewdness, treachery, revenge, murder, and every other vice which can debase the human mind, instead of offering a tribute of rational homage to that Supreme Intelligence who made, and who governs the universe. Even their priests and philosophers indulged in the most degrading and abominable practices, and entertained the most irrational notions in regard to the origin of the universe, and the moral government of the world. Most of them denied a future state of retribution, and all of them had their doubts respecting the reality of an immortal existence; and as to the doctrine of a resurrection from the dead, they never dreamed of such an event, and scouted the idea, when proposed to them, as the climax of absurdity. The glory to which their princes and generals aspired, was, to spread death and destruction among their fellow-men—to carry fire and sword, terror and dismay, and all the engines of destruction, through surrounding nations—to fill their fields with heaps of slain—to plunder the survivors of every earthly comfort, and to drag captive kings at their chariot-wheels—that they might enjoy the splendor and the honors of a triumph. What has been now stated with regard to the most enlightened nations of antiquity, will equally apply to the present inhabitants of China, of Hindostan, of the Japanese Islands, of the Birman empire, and of every other civilized nation on which the light of Revelation has never shone —with this additional consideration, that they have enjoyed an additional period of 1800 years for making further investigations; and are, at this moment, as far from the object of their pursuit as when they first commenced their researches, and not only so, but some of these nations, in modern times, have mingled with their abominable superstitions and idolatries many absurdities and horrid cruelties, which were altogether unknown among the Greek and Roman population.

Such are the melancholy results to which men have been led, when left to the guidance of unassisted reason, in the most interesting and important of all investigations. They have wandered in the mazes of error and delusion; and their researches, instead of directing and expanding our religious views, have tended only to bewilder the human mind, and to throw a deeper shade of intellectual gloom over our apostate world. After a period of six thousand years has been spent in anxious inquiries after the path to true knowledge and happiness—Ignorance, Superstition, Idolatry Vice, and Misery, still continue to sway the scepter over the great majority of the human race; and if we be allowed to reason from the past to the future, we may rest assured that, while mankind are destitute of a Guide superior to the glimmerings of depraved reason, they would be no nearer the object of their pursuit, after the lapse of *sixty thousand* years, than at the present moment. It is only in connection with the discoveries of Revelation that we can expect that the efforts of human reason and activity will be successful in abolishing the reign of Ignorance and degrading Superstition—in illuminating the benighted tribes of the Pagan world—and in causing "Righteousness, and Order, and Peace, to spring forth before all the nations." Though the Christian Religion has never yet been fully understood and recognized, in all its aspects and bearings, nor its requirements been cordially complied with, by the great body of those who profess to believe in its divine origin, yet it is only in those nations who have acknowledged its authority, and in some measure submitted to its dictates, that anything approximating to just conceptions of the Supreme Intelligence, and of its moral government, is found to prevail.

But, on the other hand, though the light of nature is of itself a feeble and insufficient guide to direct us in our views of the Supreme Intelligence, and of our eternal destination, yet it is a most dangerous and delusive error to imagine, that reason, and the study of the material world, ought to be discarded from the science of religion. The man who would discard the efforts of the human intellect, and the science of Nature, from Religion, forgets—that He who is the Author of human redemption is also the Creator and Governor of the whole system of the material universe—that it is one end of that moral renovation which the Gospel effects, to qualify us for contemplating aright the displays of Divine Perfection which the works of creation exhibit—that the visible works of God are the principal medium by which he displays the attributes of his nature to intelligent beings—that the study and contemplation of these works employ the faculties of intelligences of a superior order*—that man, had he remained in primeval innocence, would have been chiefly employed in such contemplations—that it is one main design of Divine Revelation to illustrate the operations of Providence, and the agency of God, in the formation and preservation of all things—and that the Scriptures are full of sublime descriptions of the visible creation, and of interesting references to the various objects which adorn the scenery of Nature. Without the cultivation of our reasoning powers, and an investigation of the laws and economy of Nature, we could not appreciate many of the excellent characters, the interesting aspects, and the sublime references of Revealed religion; we should lose the full evidence of those arguments by which the existence of God, and his attributes of Wisdom and Omnipotence, are most powerfully demonstrated; we should remain destitute of these sublime conceptions of the perfections and agency of Jehovah, which the grandeur and immensity of his works are calculated to inspire; we should never perceive, in its full force, the evidence of those proofs on which the Divine authority of Revelation is founded: we could not give a rational interpretation of the spirit and meaning of many parts of the Sacred Oracles; nor could we comply with those positive commands of God, which enjoin us to contemplate the wonders of his power, "to meditate on all his works, and to talk of all his doings."

Notwithstanding these and many other considerations, which show the folly of overlooking the visible manifestations of Deity in the exercises of Religion, it has long been the practice of certain theologians to depreciate the wonderful works of Jehovah, and to attempt to throw them into the shade, as if they were unworthy of our serious contemplation. In their view, to be a bad philosopher, is the surest way to become a good Christian, and to expand the views of the human mind is to endanger Christianity, and to render the design of religion abortive. They seem to consider it as a most noble triumph to the Christian cause, to degrade the material world, and to trample under foot not only the earth, but the visible heavens, as an old, shattered, and corrupted fabric, which no longer demands our study or admiration. Their expressions, in a variety of instances, would lead us almost to conclude, that they considered the economy of Nature as set in opposition to the economy of Redemption, and that it is not the same God that contrived the system of Nature who is also the "Author of eternal salvation to all them that obey him."

It is, unquestionably, both foolish and impious to overlook or to undervalue any of the modes by which the Divine Being has been pleased to make known his nature and perfections to mankind. Since he has given a display of his "Eternal power and Godhead" in the grand theater of nature, which forms the subject of scientific investigation, it was surely never intended, and would ill comport with reverence for its adorable Author, that such magnificent displays of his Power, Wisdom, and Benificence, as the material universe exhibits, should be treated, by his intelligent offspring, with indifference or neglect. It becomes us to contemplate, with adoring gratitude, every ray of our Creator's glory, whether as emanating from the light of Revelation, or as reflected from the scenery of nature around us, or as descending from those regions where stars unnumbered shine, and planets and comets run their solemn rounds. Instead of contrasting the one department of knowledge with the other, with a view of depreciating the science of nature, our duty is to derive from both as much information and instruction as they are calculated to afford, to mark the harmony of the revelations they respectively unfold; and to use the revelations of nature for the purpose of confirming, and amplifying, and carrying forward our views of the revelation contained in the Sacred Scriptures.

With regard to the revelation derived from the Sacred Records, it has been imagined by some, that it has little or no reference to the operations of the material system, and that, therefore, the study of the visible works of God can be of little importance in promoting religious knowledge and holy affections. In the sequel of this volume, I shall endeavor to show that this sentiment is extremely fallacious, and destitute of a foundation. But, in the meantime, although it were taken for granted, it would form no argument against the combination of science with religion. For it ought to be carefully remarked, that Divine Revelation is chiefly intended to instruct us in the knowledge of those truths which interest us as subjects of the *moral administration* of the Governor of the world,—or, in other words, as apostate creatures, and as moral agents. Its grand object is to develop the openings and bearings of the plan of Divine Mercy; to counteract those evil propensities and passions which sin has introduced; to inculcate those holy principles and moral laws which tend to unite mankind in harmony and love; and to produce those amiable tempers and dispositions of mind which alone can fit us for enjoying happiness, either in this world or in the world to come. For this reason doubtless it is, that the *moral* attributes of Deity are brought more prominently into view, in the Sacred Volume, than his *natural* perfections; and that those special arrangements of his Providence, which regard the *moral* renovation of our species, are particularly detailed; while the immense extent of his universal kingdom, the existence of other worlds, and their moral economy, are but slightly hinted at, or vailed in obscurity. Of such a Revelation we stood in need; and had it chiefly embraced subjects of a very different nature, it would have failed in supplying the remedies requisite for correcting the disorders which sin has introduced among mankind.—But surely it was never intended, even in a religious point of view, that the powers of the human mind, in their contemplations and researches, should be bounded by the range of subjects comprised in that revelation which is purely or chiefly of a *moral* nature; since the Almighty has exhibited so magnificent a spectacle in the universe around us, and endowed us with faculties adequate to the survey of a considerable portion of its structure, and capable of deducing from it the most noble and sublime results. To walk in the midst of this "wide-extended theater," and to overlook, or to gaze with indifference on those striking marks of Divine Omnipotence and skill which everywhere appear, is to overlook the Creator himself, and to contemn the most illustrious displays he has given of his eternal power and glory. That man's religious devotions are much to be suspected, whatever show of piety he may affect, who derives no assistance, in attempting to form some adequate conceptions of the object of his worship, from the sublime discoveries of astronomical science; from those myriads of suns and systems which form but a small portion of the Creator's immense empire!* The professing Christian, whose devotional exercises are not invigorated, and whose conceptions of Deity are not expanded, by a contemplation of the magnitude and variety of his works, may be considered as equally a stranger to the more elevated strains of piety, and to the noble emotions excited by a perception of the beautiful and the sublime.

---

* Rev. iv. 11; xv. 3, etc.

"The works of the Lord," says an inspired writer, "are *great*, and are sought out by all those who have pleasure therein." They all bear the stamp of Infinite Perfection, and serve as so many sensible mediums to exalt and expand our conceptions of Him whose invisible glories they represent and adumbrate. When contemplated in connection with the prospects opened by Divine Revelation, they tend to excite the most ardent desires after that state of enlarged vision, where the plans and operations of Deity will be more clearly unfolded—and to prepare us for bearing a part in the immortal hymn of the Church triumphant:—"Great and marvelous are thy works, Lord God Almighty; just and true are thy ways, thou King of saints." The most illustrious characters that have adorned our race in all ages, have been struck with the beauty and magnificence of the visible creation, and have devoted a certain portion of their time and attention in investigating its admirable economy and arrangement; and there can be no question, that a portion of our thoughts devoted to the study of the wondrous works of the Most High, must ultimately be conducive to the improvement of our intellectual powers, to our advancement in the Christian life, and to our preparation for the exalted employments of the eternal world.

In fine, since the researches of modern times have greatly enlarged our views of the System of Universal Nature, and of the vast extent to which the operations of the Creator are carried on in the distant regions of space,—since the late discoveries of Naturalists and Experimental Philosophers, with respect to the constitution of the atmosphere, water, light, heat, the gases, the electric, galvanic, and magnetic fluids, and the economy and instincts of animated beings, have opened to our view a bright display of Divine Wisdom, in the contrivance and arrangement of the different parts of our terrestrial habitation,—since improvements in the useful arts have kept pace with the progress of science, and have been applied to many beneficial purposes, which have ultimately a bearing on the interests and the progress of religion,—since a general desire to propagate the truths of Christianity in heathen lands now animates the mass of the religious world,—since the nations of both Continents are now aroused to burst asunder the shackles of despotism, and to inquire after rational liberty and mental improvement,—and since all these discoveries, inventions, and movements, and the energies of the human mind, from which they spring, are under the control and direction of that Omnipotent Being who made and who governs the world,—they ought to be considered as parts of those providential arrangements, in the progress of which He will ultimately accomplish the illumination of our benighted race, and make the cause of righteousness and truth to triumph among all nations. And, therefore, the enlightened Christian ought thankfully to appreciate every exhibition, and every discovery, by which his conceptions of the attributes of God, and of the grandeur of his works, may be directed and enlarged, in order that he may be qualified to "speak of the honor of his majesty, and talk of his power; to make known to the sons of men his mighty acts, and the glorious majesty of his kingdom."

---

* As some readers seem to have mistaken the Author's meaning in this and similar passages, it may be proper to state, that his meaning is not—that a knowledge of natural science is *essential* to genuine piety; but, that the person *who has an opportunity of making himself acquainted with the science of nature*, and of contemplating the wonders of the heavens in their true light, and who does not find his views of the Creator expanded, and his religious emotions elevated, by such studies, has reason to call in question the nature and the sincerity of his devotional feelings.

CHAPTER I.

OF THE NATURAL ATTRIBUTES OF THE DEITY, WITH PARTICULAR ILLUSTRATIONS OF HIS OMNIPOTENCE AND WISDOM.

SECTION I.

On the relation of the natural attributes of deity to religion.

A firm conviction of the existence of God, and a competent knowledge of his natural perfections, lie at the foundation of all religion, both natural and revealed. In proportion as our views of the perfections of Deity are limited and obscure, in a similar proportion will be our conceptions of all the relations in which he stands to his creatures, of every part of his providential procedure, and of all the doctrines and requirements of revealed religion.

By the natural or essential attributes of God, we understand such perfections as the following:—His Eternity, Omnipresence, Infinite Knowledge, Infinite Wisdom, Omnipotence, and Boundless Beneficence. These are the characters and attributes of Deity, which, we must suppose, form the chief subjects of contemplation to angels, and to all other pure intelligences—and, in investigating the displays of which, the sons of Adam would have been chiefly employed, had they continued in primeval innocence. These attributes form the groundwork of all those gracious relations in which the God of salvation stands to his redeemed people in the economy of redemption—they lie at the foundation of the whole Christian superstructure—and were they not recognized as the corner stones of that sacred edifice, the whole system of the Scripture Revelation would remain a baseless fabric. The full display of these perfections will be exhibited in the future world—the contemplation of this display will form one of the sublime employments "of the saints in light"—and to prepare us for engaging in such noble exercises, is one of the chief designs of the salvation proclaimed in the Gospel.

The Christian Revelation ought not to be considered as superseding the Religion of Nature, but as carrying it forward to perfection. It introduces the Deity to us under *new* relations corresponding to the degraded state into which we have fallen. It is superadded to our natural relations to God, and takes it for granted that these natural relations must forever subsist. It is true, indeed, that the essential attributes of God, and the principles of Natural Religion, cannot be fully discovered without the light of Revelation, as appears from the past experience of mankind in every generation; but it is equally true, that, when discovered by the aid of this celestial light, they are of the utmost importance in the Christian system, and are as essentially connected with it as the foundation of a building is with the superstructure. Many professed Christians, however, seem to think and to act as if the Christian Revelation had annulled the natural relations which subsist between man and the Deity; and hence the zealous outcry against every discussion from the pulpit, that has not a *direct* relation to what are termed the doctrines of grace. But nothing surely can be more absurd than to carry out such a principle to all its legitimate consequences. Can God ever cease to be Omnipotent, or can man ever cease to be dependent for existence on his infinite power? Can the Divine Being ever cease to be Omnipresent and Omniscient, or can man ever cease to be the object of his knowledge and superintendence? Can Infinite Wisdom ever be detached from the Almighty, or can man ever be in a situation where he will not experience the effects of his wise arrangements? Can Goodness ever fail of being an attribute of Jehovah, or can any sentient or intelligent beings exist that do not experience the effects of his bounty? Can Divine Benevolence ever cease in its operations, throughout any period of future duration, or can any intelligent beings exist, throughout any department of creation, who shall not, in a greater or less degree, experience its effects? In short, can the relation of *Creature* and *Creator* ever cease between the human race in whatever moral or physical situation they may be placed, and that Almighty Being "who giveth to all life and breath and all things!" If none of these things can possibly happen, then the relations to which we refer must be eternal and unchangeable, and must form the basis of all the other relations in which we can possibly stand to the Divine Being, either as apostate or as redeemed creatures; and, therefore they ought to be exhibited as subjects for our frequent and serious contemplation, as religious and moral agents. But, unless we make such topics a distinct subject of attention, and endeavor to acquire clear and comprehensive conceptions of our natural relations to God, we can never form a clear conception of those new and interesting relations into which we have been brought by the mediation of Jesus Christ.

If man had continued in his primitive state of integrity, he would have been forever exercised in tracing the Power, the Beneficence, and other attributes of Deity, in the visible creation alone. Now that his fallen state has rendered additional revelations necessary, in order to secure his happiness,—is he completely to throw aside those contemplations and exercises which constituted his chief employment while he remained a pure moral intelligence? Surely not. One great end of his moral renovation, by means of the Gospel, must be to enable him *to resume his primitive exercises*, and to qualify him for more enlarged views and contemplations of a similar nature, in that future world, where the physical and moral impediments which now obstruct his progress will be completely removed.

It appears highly unreasonable, and indicates a selfish disposition of mind, to magnify one class of the Divine attributes at the expense of another to extol, for example, the Mercy of God, and neglect to celebrate his Power and Wisdom—those glorious perfections, the display of which, at the formation of our globe, excited the rapture and admiration of angels, and of innocent man. All the attributes of God are *equal*, because all of them are *infinite;* and therefore to talk of *darling* attributes in the Divine Nature, as some have done, is inconsistent with reason, unwarranted by Scripture, and tends to exhibit a distorted view of the Divine character. The Divine Mercy ought to be celebrated with rapture by every individual of our fallen race; but with no less rapture should we extol the Divine Omnipotence; for the designs of Mercy cannot be accomplished without the intervention of infinite Power. Even the attribute of *Justice*—which is frequently viewed with emotions of terror—is nothing else than a branch of the Divine Benevolence, for preventing the inroads of anarchy and confusion and for securing the order and happiness of the intelligent creation. All that we hope for, in consequence of the promises of God, and of the redemption accomplished by Jesus Christ, must be founded on the conception we form of the operations of Omnipotence. An example or two may not be unnecessary for illustrating this position.

We are warranted by the Sacred Oracles, to entertain the hope that these mortal bodies of ours, after they have moldered in the dust, been dissolved into their primary elementary parts, and become the prey of devouring reptiles, during a lapse of generations or centuries—shall spring forth from the tomb to new life and beauty, and be arrayed in more glorious forms than they now wear; yea, that all the inhabitants of our globe, from Adam to the end of time, though the bodies of thousands of them have been devoured by cannibals, have become the food of fishes and of beasts of prey, and have been burned to cinders, and their ashes scattered by the winds, over the different regions of sea and land—shall be reanimated by the voice of the Son of God, and shall appear, each in his own proper person and identical body, before God the Judge of all. Now, the firmness of our hope of so astonishing an event, which seems to contradict all experience, and appears involved in such a mass of difficulties and apparent contradictions, must be in proportion to the sentiments we entertain of the Divine Intelligence, Wisdom, and Omnipotence. And where are we to find the most striking visible displays of these perfections, except in the actual operations of the Creator, within the range of our view in the material world?

Again, we are informed in the same Divine records, that, at some future period, the earth on which we now dwell shall be wrapt up in devouring flames, and its present form and constitution forever destroyed; that its redeemed inhabitants, after being released from the grave, shall be transported to a more glorious region; and that "new heavens and a new earth shall appear, wherein dwelleth righteousness." The Divine mercy having given to the faithful the promise of these astonishing revolutions, and most magnificent events, our hopes of their being fully realized must rest on the infinite wisdom and omnipotence of Jehovah; and consequently, if our views of these perfections be limited and obscure, our hope, in relation to our future destiny, will be proportionably feeble and languid; and will scarcely perform its office "as an anchor to the soul, both sure and steadfast." It is not merely by telling a person that God is all-wise and all-powerful, that a full conviction of the accomplishment of such grand events will be produced He must be made to see with his own eyes what the Almighty *has already done*, and what he is now doing, in all the regions of universal nature which lie open to our inspection; and this cannot be effected without directing his contemplations to those displays of intelligence and power which are exhibited in the structure, the economy, and the revolutions of the material world.

If the propriety of these sentiments be admitted, it will follow, that the more we are accustomed to contemplate the wonders of Divine intelligence and power, in the objects with which we are surrounded, the more deeply shall we be impressed with a conviction and a confident hope, that all the purposes of Divine mercy will ultimately be accomplished in our eternal felicity. It will also follow, that, in proportion as the mind acquires a clear, an extensive, and a reverential view of the essential attributes of the Deity, and of those truths in connection with them which are objects of contemplation common to all holy beings, in a similar proportion will it be impressed, and its attention arrested, by every other Divine subject connected with them. And it is, doubtless, owing to the want of such clear and impressive conceptions of the essential character of Jehovah, and of the first truths of religion, that the bulk of mankind are so little impressed and influenced by the leading doctrines and duties connected with the plan of the Gospel salvation, and that they entertain so many vague and untenable notions respecting the character and the objects of a superintending Providence. How often, for example, have we witnessed expressions of the foolish and limited notions which are frequently entertained respecting the operations of Omnipotence! When it has been asserted that the earth, with its load of continents and oceans, is in rapid motion through the voids of space—that the sun is ten hundred thousand times larger than the terraqueous globe —and that millions of such globes are dispersed throughout the immensity of nature,—some who have viewed themselves as enlightened Christians, have exclaimed at the impossibility of such facts, as if they were beyond the limits of Divine Power, and as if such representations were intended to turn away the mind from God and religion; while, at the same time, they have yielded a firm assent to all the vulgar notions respecting omens, apparitions, and hobgoblins, and to the supposed extraordinary powers of the professors of divination and witchcraft. How can such persons assent, with intelligence and rational conviction, to the dictates of Revelation respecting the energies of Omnipotence which will be exerted at "the consummation of all things," and in those arrangements which are to succeed the dissolution of our sublunary system! A firm belief in the Almighty Power and unsearchable Wisdom of God, as displayed in the constitution and movements of the material world, is of the utmost importance, to confirm our faith and enliven our hopes of such grand and interesting events.

Notwithstanding the considerations now stated, which plainly evince the connection of the natural perfections of God with the objects of the Christian Revelation, it appears somewhat strange that, when certain religious instructors happen to come in contact with this topic, they seem as if they were beginning to tread upon forbidden ground; and as if it were unsuitable to their office as Christian teachers, to bring forward the stupendous works of the Almighty to illustrate his nature and attributes. Instead of expatiating on the numerous sources of illustration of which the subject admits, until the minds of their hearers are thoroughly affected with a view of the essential glory of Jehovah—they dispatch the subject with two or three vague propositions, which, though logically true, make no impression upon the heart; as if they believed that such contemplations were suited only to carnal men and mere philosophers; and as if they were afraid lest the sanctity of the pulpit should be polluted by particular descriptions of those operations of the Deity which are perceived through the medium of the corporeal senses. We do not mean to insinuate that the essential attributes of God, and the illustrations of them derived from the material world, should form the sole or the chief topics of discussion in the business of religious instruction; but, if the Scriptures frequently direct our attention to these subjects—if they lie at the foundation of all accurate and extensive views of the Christian Revelation—if they be the chief subjects of contemplation to angels and all other pure intelligences, in every region of the universe—and if they have a tendency to expand the minds of professed Christians, to correct their vague and erroneous conceptions, and to promote their conformity to the moral character of God—we cannot find out the shadow of a reason why such topics should be almost, if not altogether overlooked, in the writings and the discourses of those who profess to instruct mankind in the knowledge of God and the duties of his worship.

We are informed by our Saviour himself, that "this is life eternal, to know thee the living and true God," as well as "Jesus Christ whom he hath sent." The knowledge of God in the sense here intended, must include in it the knowledge of the natural and essential attributes of the Deity, or those properties of his nature by which he is distinguished from "all the idols of the nations." Such are, his Self-existence, his All-perfect Knowledge, his Omnipresence, his Infinite Wisdom, his Boundless Goodness and Almighty Power—attributes which, as we have just now seen, lie at the foundation of all the other characters and relations of Deity revealed in the Scriptures. The acquisition of just and comprehensive conceptions of those perfections must therefore lie at the foundation of all profound veneration of the Divine Being, and of all that is valuable in religion. Destitute of such conceptions, we can neither feel that habitual *humility*, and that *reverence* of the majesty of Jehovah, which his essential glory is calculated to inspire, nor pay him that tribute of adoration and gratitude which is due to his name. Devoid of such views, we cannot exercise that cordial acquiescence in the plan of his redemption, in the arrangements of his providence, and in the requirements of his law, which the Scriptures enjoin. Yet, how often do we find persons who pretend to speculate about the mysteries of the Gospel—displaying by their flippancy of speech respecting the eternal counsels of the Majesty of heaven—by their dogmatical assertions respecting the Divine character, and the dispensations of providence — and by their pertinacious opinions respecting the laws by which God *must* regulate his own actions—that they have never felt impressive emotions of the grandeur of that Being whose "operations are unsearchable, and his ways past finding out!" Though they do not call in question his immensity and power, his wisdom and goodness, as so many abstract properties of his nature, yet, the unbecoming familiarity with which they approach this August Being, and talk about him, shows that they have never associated in their minds the stupendous displays which have been given of these perfections, in the works of his hands; and that their religion (if it may be so called) consists merely in a farrago of abstract opinions, or in an empty name.

If, then, it be admitted, that it is essentially requisite, as the foundation of religion, to have the mind deeply impressed with a clear and comprehensive view of the natural perfections of the Deity, it will follow that the ministers of religion, and all others whose province it is to communicate religious instruction, ought frequently to dwell with particularity on those proofs and illustrations which tend to convey the most definite and impressive conceptions of the glory of that Being whom we profess to adore. But from what sources are such illustrations to be derived? Is it from abstract reasonings and metaphysical distinctions and definitions, or from a survey of those objects and movements which lie open to the inspection of every observer? There can be no difficulty in coming to a decision on this point. We might affirm, with the schoolmen, that "God is a Being whose center is everywhere, and his circumference nowhere;" that "he comprehends infinite duration in every moment;" and that "infinite space may be considered as the *sensorium* of the Godhead;" but such fanciful illustrations, when strictly analyzed, will be found to consist merely of *words* without *ideas*. We might also affirm, with truth, that God is a Being of infinite perfection, glory, and blessedness—that he is without all bounds or limits, either actual or possible—that he is possessed of power sufficient to perform all things which do not imply a contradiction—that he is independent and self-sufficient—that his wisdom is unerring, and that he infinitely exceeds all other beings. But these, and other expressions of a similar kind, are *mere technical terms*, which convey no adequate, nor even tolerable notion of what they import. Beings, constituted like man, whose rational spirits are connected with an organical structure, and who derive all their knowledge through the medium of corporeal organs, can derive their clearest and most affecting notions of the Divinity chiefly through the same medium; namely, by contemplating the *effects* of his perfections, as displayed through the ample range of the visible creation And to this source of illustration, the inspired writers uniformly direct our views—"Lift up your eyes on high, and behold! who hath created these orbs? who bringeth forth their host by number, and calleth them all by their names? The everlasting God, the Lord, by the greatness of his might, for that he is strong in power,"—"He hath made the earth by his power; he hath established the world by his wisdom; he hath stretched out the heavens by his understanding."—These writers do not perplex our minds by a multitude of technical terms and subtile reasonings; but lead us directly to the source whence our most ample conceptions of Deity are to be derived, that, from a steady and enlightened contemplation of the effects, we may learn the greatness of the Cause; and their example in this respect ought, doubtless, to be a pattern for every religious instructor.

SECTION II.

ILLUSTRATIONS OF THE OMNIPOTENCE OF THE DEITY.

In order to elucidate more distinctly what has been now stated, I shall select a few illustrations of some of the natural attributes of the Deity. And, in the first place, I shall offer a few considerations which have a tendency to direct and to amplify our conceptions of Divine Power.

Omnipotence is that attribute of the Divine Being, by which he can accomplish everything that does not imply a contradiction—however far it may transcend the comprehension of finite minds. By his power the vast system of universal nature was called from nothing into existence, and is continually supported in all its movements, from age to age.—In elucidating this perfection of God, we might derive some striking illustrations from the records of his dispensations toward man, in the early ages of the world—When he overwhelmed the earth with a deluge, which covered the tops of the highest mountains, and swept the crowded population of the ancient world into a watery grave—when he demolished Sodom and Gomorrah, and the cities around them, with fire from heaven—when he slew all the first-born of Egypt, and turned their rivers into blood—when he divided the Red sea and the waters of Jordan, before the tribes of Israel—when he made the earth open its jaws and swallow up Korah and all his company—and when he caused mount Sinai to smoke and tremble at his presence. But these and similar events, however awful, astonishing, and worthy of remembrance, were only *transitory* exertions of Divine power, and are not calculated, and were never intended, to impress the mind in so powerful a manner as those displays of Omnipotence which are exhibited in the ordinary movements of the material universe. We have no hesitation in asserting, that, with regard to this attribute of the Divinity, there is a more grand and impressive display in the Works of Nature than in all the events recorded in the Sacred History. Nor ought this remark to be considered as throwing the least reflection on the fullness and sufficiency of the Scripture Revelation; for that revelation, as having a special reference to a *moral* economy, has for its object, to give a more particular display of the *moral* than of the *natural* perfections of God. The miracles to which we have now referred, and every other supernatural fact recorded in the Bible, were not intended so much to display the *plenitude* of the power of the Deity, as to bear testimony to the Divine mission of particular messengers, and to confirm the truths they declared. It was not, for example, merely to display the energies of Almighty power, that the waters of the Red sea were dried up before the thousands of Israel, but to give a solemn and striking attestation to all concerned, that the Most High God had taken this people under his peculiar protection—that he had appointed Moses as their leader and legislator—and that they were bound to receive and obey the statutes he delivered. The most appropriate and impressive illustrations of Omnipotence are those which are taken from the *permanent* operations of Deity, which are visible every moment in the universe around us; or, in other words, those which are derived from the facts which have been observed in the material world, respecting *magnitude* and *motion.*

In the first place, *the immense quantity of matter* contained in the universe, presents a most striking display of Almighty power.

In endeavoring to form a definite notion on this subject, the mind is bewildered in its conceptions, and is at a loss where to begin or to end its excursions. In order to form something approximating to a well-defined idea, we must pursue a train of thought commencing with those magnitudes which the mind can easily grasp, proceeding through all the higher gradations of magnitude, and fixing the attention on every portion of the chain, until we arrive at the object or magnitude of which we wish to form a conception. We must endeavor, in the first place, to form a conception of the bulk of the world in which we dwell, which, though only a point in comparison of the whole material universe, is in reality, a most astonishing magnitude, which the mind cannot grasp without a laborious effort. We can form some definite idea of those protuberant masses we denominate *hills,* which rise above the surface of our plains; but were we transported to the mountainous scenery of Switzerland, to the stupendous range of the Andes in South America, or to the Himalayan mountains in India, where masses of earth and rocks, in every variety of shape, extend several hundreds of miles in different directions, and rear their projecting summits beyond the region of the clouds—we should find some difficulty in forming an adequate conception of the objects of our contemplation. For (to use the words of one who had been a spectator of such scenes), "Amidst those trackless regions of intense silence and solitude, we cannot contemplate, but with feelings of awe and admiration, the enormous masses of variegated matter which lie around, beneath, and above us. The mind labors, as it were, to form a definite idea of those objects of oppressive grandeur, and feels unable to grasp the august objects which compose the surrounding scene." But what are all these mountainous masses, however variegated and sublime, when compared with the bulk of the whole earth? Were they hurled from their bases, and precipitated into the vast Pacific ocean, they would all disappear in a moment, except perhaps a few projecting tops, which, like a number of small islands, might be seen rising a few fathoms above the surface of the waters.

The earth is a globe, whose diameter is nearly 8000 miles, and its circumference about 25,000, and consequently, its surface contains nearly two hundred millions of square miles—a magnitude too great for the mind to take in at *one* conception. In order to form a tolerable conception of the whole, we must endeavor to take a leisurely survey of its different parts. Were we to take our station on the top of a mountain, of a moderate size, and survey the surrounding landscape, we should perceive an extent of view stretching 40 miles in every direction, forming a circle 80 miles in diameter, and 250 in circumference, and comprehending an area of 5000 square miles. In such a situation, the terrestrial scene around and beneath us—consisting of hills and plains, towns and villages, rivers and lakes—would form one of the largest objects which the eye, or even the imagination, can steadily grasp at one time. But such an object, grand and extensive as it is, forms no more than the *forty thousandth part* of the terraqueous globe; so that, before we can acquire an adequate conception of the magnitude of our own world, we must conceive 40,000 landscapes, of a similar extent, to pass in review before us; and, were a scene, of the magnitude now stated, to pass before us every hour, until all the diversified scenery of the earth were brought under our view, and were twelve hours a-day allotted for the observation, it would require nine years and forty-eight days before the whole surface of the globe could be contemplated, even in this *general* and *rapid* manner. But, such a variety of successive landscapes passing before the eye, even although it were possible to be realized, would convey only a very vague and imperfect conception of the scenery of our world; for objects at the distance of forty miles cannot be distinctly perceived; the only view which would be satisfactory would be that which is comprehended within the range of three or four miles from the spectator.

Again, I have already stated, that the surface of the earth contains nearly 200,000,000 of square miles.—Now, were a person to set out on a minute survey of the terraqueous globe, and to travel until he passed along every square mile on its surface, and to continue his route without intermission, at the rate of 30 miles every day, it would require 18,264 years before he could finish his tour, and complete the survey of "this huge rotundity on which we tread:" so that, had he commenced his excursion on the day on which Adam was created, and continued it to the present hour, he would not have accomplished one-third part of this vast tour.

In estimating the size and extent of the earth, we ought also to take into consideration, the vast variety of objects with which it is diversified, and the numerous animated beings with which it is stored;—the great divisions of land and water, the continents, seas, and islands, into which it is distributed; the lofty ranges of mountains which rear their heads to the clouds; the unfathomable abysses of the ocean; its vast subterraneous caverns and burning mountains; and the lakes, rivers, and stately forests, with which it is so magnificently adorned;—the many millions of animals, of every size and form, from the elephant to the mite, which traverse its surface; the numerous tribes of fishes, from the enormous whale to the diminutive shrimp, which "play" in the mighty ocean; the aerial tribes which sport in the regions above us, and the vast mass of the surrounding atmosphere, which encloses the earth and all its inhabitants, as "with a swaddling band." The immense variety of beings with which our terrestrial habitation is furnished, conspires, with every other consideration, to exalt our conceptions of that Power by which our globe, and all that it contains, were brought into existence.

The preceding illustrations, however, exhibit the vast extent of the earth, considered only as a mere superficies. But we know that the earth is a solid globe, whose specific gravity is nearly five times denser than water, or about twice as dense as the mass of earth and rocks which compose its surface. Though we cannot dig into its bowels beyond a mile in perpendicular depth, to explore its hidden wonders, yet we may easily conceive what a vast and indescribable mass of matter must be contained between the two opposite portions of its external circumference, reaching 8000 miles in every direction. The solid contents of this ponderous ball is no less than 263,858,149,120 cubical miles—a mass of material substance of which we can form but a very faint and imperfect conception: in proportion to which, all the lofty mountains which rise above its surface, are less than a few grains of sand, when compared with the largest artificial globe. Were the earth a hollow sphere, surrounded merely with an external shell of earth and water ten miles thick, its internal cavity would be sufficient to contain a quantity of materials *one hundred and thirty-three times* greater than the whole mass of continents, islands, and oceans, on its surface, and the foundations on which they are supported. We have the strongest reasons, however, to conclude, that the earth, in its general structure, is one solid mass, from the surface to the center, excepting, perhaps, a few caverns scattered here and there amidst its subterranean recesses; and that its density gradually increases from its surface to its central regions. What an enormous mass of materials, then, is comprehended within the limits of the globe on which we tread! The mind labors, as it were, to comprehend the mighty idea, and, after all its exertion, feels itself unable to take in such an astonishing magnitude at *one* comprehensive grasp. How great must be the power of that Being who commanded it to spring from nothing into existence, who "measures the ocean in the hollow of his hand, who weigheth the mountains in scales, and hangeth the earth upon nothing!"

It is essentially requisite, before proceeding to the survey of objects and magnitudes of a superior order, that we should endeavor, by such a train of thought as the preceding, to form some tolerable and clear conception of the bulk of the globe we inhabit; for it is the only body we can use as a standard of comparison to guide the mind in its conceptions, when it roams abroad to other regions of material existence. And from what has been now stated, it appears, that we have no *adequate* conception of a magnitude of so vast an extent; or at least, that the mind cannot, in any one instant, form to itself a distinct and comprehensive idea of it, in any measure corresponding to the reality.

Hitherto, then, we have fixed only on a determinate magnitude—on a scale of a few inches, as it were, in order to assist us in our measurement and conception of magnitudes still more august and astonishing. When we contemplate by the light of science, those magnificent globes which float around us in the concave of the sky, the earth, with all its sublime scenery, stupendous as it is, dwindles into an inconsiderable ball. If we pass from our globe to some of the other bodies of the planetary system, we shall find that one of these stupendous orbs is more than 900 times the size of our world, and encircled with a ring 200,000 miles in diameter, which would nearly reach from the earth to the moon, and would enclose within its vast circumference several hundreds of worlds as large as ours. Another of these planetary bodies, which appears to the vulgar eye only as a brilliant speck on the vault of heaven, is found to be of such a size, that it would require 1400 globes of the bulk of the earth to form one equal to it in dimensions. The whole of the bodies which compose the solar system (without taking the sun and the comets into account) contain a mass of matter 2500 times greater than that of the earth. The sun itself is 520 times larger than all the planetary globes taken together; and one million three hundred thousand times larger than the terraqueous globe. This is one of the most glorious and magnificent visible objects which either the eye or the imagination can contemplate; especially when we consider, what perpetual, and incomprehensible, and powerful influence it exerts—what warmth, and beauty, and activity it diffuses, not only on the globe we inhabit, but over the more extensive regions of surrounding worlds. Its energy extends to the utmost limits of the planetary system—to the planet Herschel which revolves at the distance of 1800 millions of miles from its surface, and there it dispenses light, and color, and comfort, to all the beings connected with that far distant orb, and to all the moons which roll around it.

Here the imagination begins to be overpowered and bewildered in its conceptions of magnitude, when it has advanced scarcely a single step in its excursions through the material world. For it is highly probable, that all the matter contained within the limits of the solar system, incomprehensible as its magnitude appears, bears a smaller proportion to the whole mass of the material universe, than a single grain of sand to all the particles of matter contained in the body of the sun and his attending planets.

If we extend our views from the solar system to the starry heavens, we have to penetrate, in our imagination, a space which the swiftest ball that was ever projected, though in perpetual motion, would not traverse in ten hundred thousand years. In those trackless regions of immensity, we behold an assemblage of resplendent globes, similar to the sun in size and in glory, and doubtless accompanied with a retinue of worlds, revolving like our own around their attractive influence. The immense distance at which the nearest stars are known to be placed proves that they are bodies of a prodigious size, not inferior to our own sun, and that they shine not by reflected rays, but by their own native light. But bodies encircled with such refulgent splendor would be of little use in the economy of Jehovah's empire, unless surrounding worlds were cheered by their benign influence, and enlightened by their beams. Every star is, therefore, with good reason, concluded to be a sun, no less spacious than ours, surrounded by a host of planetary globes, which revolve around it as a center, and derive from it light and heat and comfort. Nearly a thousand of these luminaries may be seen in a clear winter night by the naked eye; so that a mass of matter equal to a thousand solar systems, or to *thirteen hundred and twenty millions of globes of the size of the earth*, may be perceived by every common observer in the canopy of heaven. But all the celestial orbs which are perceived by the unassisted sight do not form the eighty thousandth part of those which may be descried by the help of optical instruments. The telescope has enabled us to descry in certain spaces in the heavens, thousands of stars where the naked eye could scarcely discern twenty. The late celebrated astronomer, Dr. Herschel, has informed us, that in the most crowded parts of the Milky-way, when exploring that region with his best glasses, he has had fields of view which contained no less than 588 stars, and these were continued for many minutes; so that "in one quarter of an hour's time there passed no less than *one hundred and sixteen thousand stars* through the field of view of his telescope."

It has been computed, that nearly *one hundred millions* of stars might be perceived by the most perfect instruments, were all the regions of the sky thoroughly explored; and yet, all this vast assemblage of suns and worlds, when compared with what lies beyond the utmost boundaries of human vision, in the immeasurable spaces of creation, may be no more than as the smallest particle of vapor to the immense ocean. Immeasurable regions of space lie beyond the utmost limits of mortal view, into which even imagination itself can scarcely penetrate, and which are, doubtless, replenished with the operations of Divine Wisdom and Omnipotence. For it cannot be supposed that a being so diminutive as man, whose stature scarcely exceeds six feet—who vanishes from the sight at the distance of a league—whose whole habitation is invisible from the nearest star—whose powers of vision are so imperfect, and whose mental faculties are so limited—it cannot be supposed that man, who "dwells in tabernacles of clay, who is crushed before the moth," and chained down, by the force of gravitation, to the surface of a small planet, should be able to descry the utmost boundaries of the empire of Him who fills immensity, and dwells in "light inapproachable." That portion of his dominions, however, which lies within the range of our view, presents such a scene of magnificence and grandeur, as must fill the mind of every reflecting person with astonishment and reverence, and constrain him to exclaim, "Great is our Lord, and of great power, his understanding is infinite." "When I consider thy heavens, the work of thy fingers, the moon and the stars, which thou hast ordained; what is man, that thou art mindful of him?" "I have heard of thee by the hearing of the ear;" I have listened to subtile disquisitions on thy character and perfections, and have been but little affected; "but now mine eye *seeth* thee: wherefore I humble myself, and repent in dust and ashes."

In order to feel the full force of the impression made by such contemplations, the mind must pause at every step in its excursions through the boundless regions of material existence; for it is not by a mere attention to the figures and numbers by which the magnitudes of the great bodies of the universe are expressed, that we arrive at the most distinct and ample conceptions of objects so grand and overwhelming. The mind, in its intellectual range, must dwell on every individual scene it contemplates, and on the various objects of which it is composed. It must add scene to scene, magnitude to magnitude, and compare smaller objects with greater—a range of mountains with the whole earth, the earth with the planet Jupiter, Jupiter with the sun, the sun with a thousand stars, a thousand stars with eighty millions, and eighty millions with all the boundless extent which lies beyond the limits of mortal vision; and, at every step of this mental process, sufficient time must be allowed for the imagination to expatiate on the objects before it, until the ideas approximate, as near as possible, to the reality. In order to form a comprehensive conception of the extent of the terraqueous globe, the mind must dwell on an extensive landscape, and the objects with which it is adorned: it must endeavor to survey the many thousands of diversified landscapes which the earth exhibits—the hills and plains, the lakes and rivers and mountains, which stretch in endless variety over its surface: it must dive into the vast caverns of the ocean—penetrate into the subterraneous regions of the globe, and wing its way, amidst clouds and tempests, through the surrounding atmosphere. It must next extend its flight through the more expansive regions of the solar system—realizing, in imagination, those magnificent scenes which can be descried neither by the naked eye nor by the telescope; and comparing the extent of our sublunary world with the more magnificent globes that roll around us. Leaving the sun and all his attendant planets behind, until they have diminished to the size of a small twinkling star, it must next wing its way to the starry regions, and pass from one system of worlds to another, from one Nebula* to another, from one region of Nebulæ to another, until it arrive at the utmost boundaries of creation which human genius has explored. It must also endeavor to extend its flight beyond all that is visible by the best telescopes, and expatiate at large in that boundless expanse into which no human eye has yet penetrated, and which is doubtless replenished with other worlds, and systems, and firmaments, where the operations of infinite power and beneficence are displayed, in endless variety, throughout the illimitable regions of space.

---

* For an account of the *Nebulæ*, see ch. ii, Art. *Astronomy*.

Here, then, with reverence, let us pause and wonder! Over all this vast assemblage of material existence, God presides. Amidst the diversified objects and intelligences it contains, he is eternally and essentially present. By his unerring wisdom, all its complicated movements are directed. By his Almighty fiat, it emerged from nothing into existence, and is continually supported from age to age. "HE SPAKE, AND IT WAS DONE; HE COMMANDED, AND IT STOOD FAST." "By the word of the Lord were the heavens made, and all the host of them by the spirit of his mouth." What an astonishing display of Divine power is here exhibited to our view! How far transcending all finite comprehension must be the energies of Him who only "spake, and it was done;" who only gave the command, and this mighty system of the universe, with all its magnificence, started into being! The infinite ease with which this vast fabric was reared, leads us irresistibly to conclude that there are powers and energies in the Divine mind which have never yet been exerted, and which may unfold themselves to intelligent beings, in the production of still more astonishing and magnificent effects, during an endless succession of existence. That man who is not impressed with a venerable and overwhelming sense of the power and majesty of Jehovah by such contemplations, must have a mind incapable of ardent religious emotions, and unqualified for appreciating the grandeur of that Being "whose kingdom ruleth over all." And shall such ennobling views be completely withheld from a Christian audience? Shall it be considered as a matter of mere indifference whether their views of the Creator's works be limited to the sphere of a few miles around them, or extended to ten thousand worlds?—whether they shall be left to view the operations of the Almighty throughout eternity past and to come, as confined to a small globe, placed in the immensity of space, with a number of brilliant studs fixed in the arch of heaven, at a few miles' distance, or, as extending through the boundless dimensions of space?—whether they shall be left to entertain no higher idea of the Divine Majesty than what may be due to one of the superior orders of the seraphim or cherubim; or, whether they shall be directed to form the most august conceptions of the King eternal, immortal, and invisible, corresponding to the displays he has given of his glory in his visible works? If it be not, both reason and piety require that such illustrations of the Divine perfections should occasionally be exhibited to their view.

In the next place, the *rapid motions* of the great bodies of the universe, no less than their magnitudes, display the infinite power of the Creator.

We can acquire accurate ideas of the relative velocities of moving bodies, only by comparing the motions with which we are familiar with one another, and with those which lie beyond the general range of our minute inspection. We can acquire a pretty accurate conception of the velocity of a ship impelled by the wind—of a steam-boat—of a race-horse—of a bird darting through the air—of an arrow flying from a bow—and of the clouds when impelled by a stormy wind. The velocity of a ship is from 8 to 12 miles an hour,—of a race-horse, from 20 to 30 miles,—of a bird, say from 50 to 60 miles, and of the clouds, in a violent hurricane, from 80 to 100 miles an hour. The motion of a ball from a loaded cannon is incomparably swifter than any of the motions now stated: but of the velocity of such a body we have a less accurate idea; because, its rapidity being so great, we cannot trace it distinctly by the eye through its whole range, from the mouth of the cannon to the object against which it is impelled By experiments, it has been found that its rate of motion is from 480 to 800 miles in an hour, but it is retarded every moment by the resistance of the air and the attraction of the earth. This velocity, however, great as it is, bears no sensible proportion to the rate of motion which is found among the celestial orbs. That such enormous masses of matter should move at all is wonderful: but when we consider the amazing velocity with which they are impelled, we are lost in astonishment. The planet Jupiter, in describing its circuit round the sun, moves at the rate of 29,000 miles an hour. The planet Venus, one of the nearest and most brilliant of the celestial bodies, and about the same size as the earth, is found to move through the spaces of the firmament at the rate of 76,000 miles an hour; and the planet Mercury, with a velocity of no less than 105,000 miles an hour, or 1750 miles in a minute—a motion two hundred times swifter than that of a cannon ball.

These velocities will appear still more astonishing, if we consider the magnitude of the bodies which are thus impelled, and the immense forces which are requisite to carry them along in their courses. However rapidly a ball flies from the mouth of a cannon, it is the flight of a body of only a *few inches* in diameter; but one of the bodies, whose motion has been just now stated, is *eighty-nine thousand miles* in diameter, and would comprehend within its vast circumference more than a thousand globes as large as the earth.—Could we contemplate such motions from a fixed point, at the distance of only a few hundreds of miles from the bodies thus impelled—it would raise our admiration to its highest pitch, it would overwhelm all our faculties, and, in our present state would produce an impression of awe, and even of terror, beyond the power of language to express. The earth contains a mass of matter equal in weight to at least 2,200,000,000,000,000,000,000, or more than two thousand trillions of tons, supposing its mean density to be only about 2½ times greater than water. To move this ponderous mass, a single inch beyond its position, were it fixed in a quiescent state, would require a mechanical force almost beyond the power of numbers to express. The physical force of all the myriads of intelligences within the bounds of the planetary system, though their powers were far superior to those of man, would be altogether inadequate to the production of such a motion. How much more must be the force requisite to impel it with a velocity one hundred and forty times swifter than a cannon ball, or 68,000 miles an hour, the actual rate of its motion, in its course round the sun! But whatever degree of mechanical power would be requisite to produce such a stupendous effect, it would require a force one hundred and fifty times greater to impel the planet Jupiter, in its actual course, through the heavens! Even the planet Saturn, one of the slowest moving bodies of our system, a globe 900 times larger than the earth, is impelled through the regions of space, at the rate of 22,000 miles an hour, carrying along with it two stupendous rings, and seven moons larger than ours, through its whole course round the central luminary. Were we placed within a thousand miles of this stupendous globe (a station which superior beings may occasionally occupy), where its hemisphere, encompassed by its magnificent rings, would fill the whole extent of our vision—the view of such a ponderous and glorious object, flying with such amazing velocity before us, would infinitely exceed every idea of grandeur we can derive from terrestrial scenes, and overwhelm our powers with astonishment and awe. Under such an emotion, we could only exclaim, "GREAT AND MARVELOUS ARE THY WORKS, LORD GOD ALMIGHTY!" The ideas of *strength* and *power* implied in the impulsion of such enormous masses of matter, through the illimitable tracts of space, are forced upon the mind with irresistible energy, far surpassing what any abstract propositions or reasonings can convey; and, constrain us to exclaim, "Who is a strong Lord like unto thee! Thy right hand has become glorious in power! The Lord God omnipotent reigneth!"

If we consider the *immense number* of bodies thus impelled through the vast spaces of the universe—the rapidity with which the *comets*, when near the sun, are carried through the regions they traverse,—if we consider the high probability, if not absolute certainty, that the sun, with all its attendant planets and comets, is impelled with a still greater degree of velocity toward some distant region of space, or around some wide circumference—that all the thousands of systems of that nebula to which the sun belongs are moving in a similar manner—that all the nebulæ in the heavens are moving around some magnificent central body,—in short, that all the suns and worlds in the universe are in rapid and perpetual motion, as constituent portions of one grand and boundless empire, of which Jehovah is the Sovereign—and if we consider still further, that all these mighty movements have been going on, without intermission, during the course of many centuries, and some of them, perhaps, for myriads of ages before the foundation of our world was laid—it is impossible for the human mind to form any adequate idea of the stupendous forces which are in incessant operation throughout the unlimited empire of the Almighty. To estimate such mechanical force, even in a single instance, completely baffles the mathematician's skill, and sets the power of numbers at defiance. "Language," and figures, and comparisons, are "lost in wonders so sublime," and the mind, overpowered with such reflections, is irresistibly led upward to search for the cause in that OMNIPOTENT BEING who upholds the pillars of the universe—the thunder of whose power none can comprehend.

While contemplating such august objects, how emphatic and impressive appears the language of the Sacred Oracles: "Canst thou by searching find out God? Canst thou find out the Almighty unto perfection? Great things doth he which we cannot comprehend. Thine, O Lord, is the greatness, and the glory, and the majesty; for all that is in heaven and earth is thine. Among the gods there is none like unto thee, O Lord; neither are there any works like unto thy works. Thou art great, and dost wondrous things: thou art God alone. Hast thou not known, hast thou not heard, that the everlasting God, the Lord, the Creator of all things, fainteth not, neither is weary? there is no searching of his understanding. Let all the earth fear the Lord, let all the inhabitants of the world stand in awe of him; for he *spake*, and *it was done;* he commanded, and it stood fast."

Again, the *immense spaces* which surround the heavenly bodies, and in which they perform their revolutions, tend to expand our conceptions on this subject, and to illustrate the magnificence of the Divine operations. In whatever point of view we contemplate the scenery of the heavens, an idea of grandeur irresistibly bursts upon the mind; and if empty space can, in any sense, be considered as an object of sublimity, nothing can fill the mind with a grander idea of magnitude and extension than the amplitude of the scale on which planetary systems are constructed. Around the body of the sun there is allotted a cubical space, 3600 millions of miles in diameter, in which eleven planetary globes revolve—every one being separated from another, by intervals of many millions of miles. The space which surrounds the utmost limits of our system, extending, in every direction, to the nearest fixed stars, is at least 40,000,000,000,000, or forty billions of miles in diameter; and, it is highly probable, that every star is surrounded by a space of equal or even of greater extent. A body impelled with the greatest velocity which art can produce—a cannon ball, for instance—would require twenty years to pass through the space that intervenes between the earth and the sun, and four millions seven hundred thousand years ere it could reach the nearest star. Though the stars seem to be crowded together in clusters, and some of them almost to touch one another, yet the distance between any two stars which seem to make the nearest approach, is such as neither words can express, nor imagination fathom. These immense spaces are as unfathomable, on the one hand, as the magnitude of the bodies which move in them, and their prodigious velocities are incomprehensible, on the other; and they form a part of those magnificent proportions according to which the fabric of universal nature was arranged—all corresponding to the majesty of that infinite and incomprehensible Being, "who measures the ocean in the hollow of his hand, and meteth out the heavens with a span." How wonderful that bodies at such prodigious distances should exert a mutual influence on one another! that the moon, at the distance of 240,000 miles, should raise tides in the ocean, and currents in the atmosphere! that the sun, at the distance of ninety-five millions of miles, should raise the vapors, move the ocean, direct the course of the winds, fructify the earth, and distribute light, and heat, and color, through every region of the globe! yea, that its attractive influence and fructifying energy should extend even to the planet Herschel, at the distance of eighteen hundred millions of miles! So that, in every point of view in which the universe is contemplated, we perceive the same *grand scale* of operation by which the Almighty has arranged the provinces of his universal kingdom.

We would now ask, in the name of all that is sacred, whether such magnificent manifestations of Deity ought to be considered as irrelevant in the business of religion, and whether they ought to be thrown completely into the shade, in the discussions which take place on religious topics, in "the assemblies of the saints!" If religion consist in the intellectual apprehension of the perfections of God, and in the moral effects produced by such an apprehension—if all the rays of glory emitted by the luminaries of heaven are only so many reflections of the grandeur of Him who dwells in light inapproachable—if they have a tendency to assist the mind in forming its conceptions of that ineffable Being, whose uncreated glory cannot be directly contemplated—and if they are calculated to produce a sublime and awful impression on all created intelligences,—shall we rest contented with a less glorious idea of God than his works are calculated to afford? Shall we disregard the works of the Lord, and contemn the operations of his hands, and that too in the face of all the invitations on this subject addressed to us from heaven? For thus saith Jehovah—"Lift up your eyes on high, and behold, who hath created these things—who bringeth forth their host by number?—I the Lord, who maketh all things, who stretched forth the heavens alone, and spread abroad the earth by myself; all their host have I commanded." And if, at the command of God, we lift our eyes to the "firmament of his power," surely we ought to do it not with a "brute unconscious gaze," not with the vacant stare of a savage, not as if we were still enveloped with the mists and prejudices of the dark ages—but as surrounded by that blaze of light which modern science has thrown upon the scenery of the sky, in order that we may contemplate, with fixed attention, all that enlightened reason, aided by the nicest observations, has ascertained respecting the magnificence of the celestial orbs. To overlook the sublime discoveries of modern times, to despise them, or to call in question their reality as some religionists have done, because they bring to our ears such astonishing reports of "the eternal power" and majesty of Jehovah—is to act as if we were afraid lest the Deity should be represented as more grand and magnificent than he really is, and as if we would be better pleased to pay him a less share of homage and adoration than is due to his name.

Perhaps some may be disposed to insinuate, that the views now stated are above the level of ordinary comprehension, and founded too much on scientific considerations, to be stated in detail to a common audience. To any insinuations of this kind it may be replied, that such illustrations as those to which we have referred, are more easily comprehended than many of those abstract discussions to which they are frequently accustomed; since they are definite and tangible, being derived from those objects which strike the senses and the imagination. Any person of common understanding may be made to comprehend the leading ideas of extended space, magnitude, and motion, which have been stated above, provided the descriptions be sufficiently simple, clear, and well-defined; and should they be at a loss to comprehend the principles on which the conclusions rest, or the mode by which the magnificence of the works of God has been ascertained, an occasional reference to such topics would excite them to inquiry and investigation, and to the exercise of their powers of observation and reasoning on such subjects—which are too frequently directed to far less important objects.

The following illustration, however, stands clear of every objection of this kind, and is level to the comprehension of every man of common sense:—Either the earth moves round its axis once in twenty-four hours—or the sun, moon, planets, comets, stars, or the whole frame of the universe, move around the earth in the same time. There is no alternative, or third opinion, that can be formed on this point. If the earth revolve on its axis every twenty-four hours, to produce the alternate succession of day and night, the portions of its surface about the equator must move at the rate of more than a thousand miles an hour, since the earth is more than twenty-four thousand miles in circumference. This view of the fact, when attentively considered, furnishes a most sublime and astonishing idea. That a globe of so vast dimensions, with all its load of mountains, continents, and oceans, comprising within its circumference a mass of two hundred and sixty-four thousand millions of cubical miles, should whirl round with so amazing a velocity, gives us a most august and impressive conception of the greatness of that Power which first set it in motion, and continues the rapid whirl from age to age!—Though the huge masses of the Alpine mountains were in a moment detached from their foundations, carried aloft through the regions of the air, and tossed into the Mediterranean sea, it would convey no idea of a force equal to that which is every moment exerted, if the earth revolve on its axis. But should the motion of the earth be called in question, or denied, the idea of force, or power, will be indefinitely increased.—For, in this case, it must necessarily be admitted that the heavens, with all the innumerable hosts of stars, have a diurnal motion around our globe; which motion must be inconceivably more rapid than that of the earth, on the supposition of its motion. For, in proportion as the celestial bodies are distant from the earth, in the same proportion would be the rapidity of their movements. The sun, on this supposition, would move at the rate of 414,000 miles in a minute; the nearest stars at the rate of fourteen hundred millions of miles in a *second;* and the most distant luminaries, with a degree of swiftness which no numbers could express.* Such velocities, too, would be the rate of motion, not merely of a single globe like the earth, but of all the ten thousand times ten thousand spacious globes that exist within the boundaries of creation. This view conveys an idea of power still more august and overwhelming than any of the views already stated, and we dare not presume to assert that such a degree of physical force is beyond the limits of Infinite perfection: but on the supposition it existed, it would confound all our ideas of the wisdom and intelligence of the Divine mind, and would appear altogether inconsistent with the character which the Scriptures give us of the Deity as "the only-wise God." For it would exhibit a stupendous system of means altogether disproportioned to the end intended; namely, to produce the alternate succession of day and night to the inhabitants of our globe, which is more beautifully and harmoniously effected by a single rotation on its axis, as is the case with the other globes which compose the planetary system. Such considerations, however, show us that, on whatever hypothesis, whether on the vulgar or the scientific, or in whatever other point of view the frame of nature may be contemplated, the mind is irresistibly impressed with ideas of power, grandeur, and magnificence. And, therefore, when an inquiring mind is directed to contemplate the works of God, on any hypothesis it may choose, it has a tendency to rouse reflection, and to stimulate the exercise of the moral and intellectual faculties, on objects which are worthy of the dignity of immortal minds.

We may now be, in some measure, prepared to decide, whether illustrations of the Omnipotence of the Deity, derived from the system of the material world, or those vague and metaphysical disquisitions which are generally given in theological systems, be most calculated to impress the mind, and to inspire it with reverence and adoration. The following is a description given of this attribute of God, by a well-known systematic writer, who has generally been considered as a judicious and orthodox divine:—

"God is Almighty.† This will evidently appear, in that, if he be infinite in all his other perfections, he must be so in power; thus, if he be omniscient, he knows what is possible or expedient to be done; and if he be an infinite sovereign, he wills whatever shall come to pass. Now this knowledge would be insignificant, and his power inefficacious, were he not infinite in power, or almighty. Again, this might be argued from his justice, either in rewarding or punishing; for, if he were not infinite in power, he could do neither of these, at least so far as to render him the object of that desire or fear, which is agreeable to the nature of these perfections; neither could infinite faithfulness accomplish all the promises which he hath made, so as to excite that trust and dependence, which is a part of religious worship; nor could he say without limitation, as he does, *I have spoken it, I will also bring it to pass: I have purposed it, I will also do it.*[*] But since power is visible in, and demonstrated by its effects, and infinite power by those effects which cannot be produced by a creature, we may observe the almighty power of God in all his works, both of nature and grace; thus his eternal power is understood, as the apostle says, *by the things that are made;*[†] not that there was an eternal production of things, but the exerting this power in time, proves it to be infinite and truly divine; for no creature can produce the smallest particle of matter out of nothing, much less furnish the various species of creatures with those endowments in which they excel one another, and set forth their Creator's glory. And the glory of his power is no less visible in the works of providence, whereby he upholds all things, disposes of them according to his pleasure, and brings about events which only he who has an almighty arm can effect."[‡]

---

* See Appendix, Note 1.

† Rev. i. 18; iv. 8.

This is the whole that Dr. Ridgely judges it necessary to state in illustration of the attribute of Omnipotence, except what he says in relation to its operation in "the work of grace," in "the propagation and success of the Gospel," etc.; subjects to which the idea of power, or physical energy, does not properly apply. Such, however, are the meager and abstract disquisitions generally given by most systematic writers. There is a continual play on the term "Infinite," which, to most minds conveys no idea at all, unless it be associated with ample conceptions of motion, magnitude, and extension; and it is constantly applied to subjects to which it was never intended to apply, such as "infinite faithfulness, infinite justice, infinite truth," etc.; an application of the term which is never sanctioned by Scripture, and which has a tendency to introduce confusion into our conceptions of the perfections of God.—Granting that the statements and reasonings in such an extract as the above were unquestionable, yet what impression can they make upon the mind? Would an ignorant person feel his conception of the Divinity much enlarged, or his moral powers aroused by such vague and general statements? And, if not, it appears somewhat unaccountable, that those sources of illustration which would convey the most ample and definite views of the "eternal power" and glory of God, should be studiously concealed from the view.—Vague descriptions and general views of any object will never be effectual in awakening the attention and arresting the faculties of the mind. The heart will always remain unimpressed, and the understanding will never be thoroughly excited in its exercise, unless the intellect have presented before it a well-defined and interesting object, and be enabled to survey it in its various aspects; and this object must always have a relation to the material world, whether it be viewed in connection with religion or with any other subject.

Thus, I have endeavored, in the preceding sketches, to present a few detached illustrations of the Omnipotence and grandeur of the Deity, as displayed in the vast magnitude of the material universe—the stupendous velocities of the celestial bodies—and in the immeasurable regions of space which surround them, and in which their motions are performed. Such a magnificent spectacle as the fabric of the universe presents—so majestic, godlike, and overwhelming, to beings who dwell "in tabernacles of clay"—was surely never intended to be overlooked, or to be gazed at with indifference, by creatures endowed with reason and intelligence, and destined to an immortal existence. In forming a universe composed of so many immense systems and worlds, and replenished with such a variety of sensitive and intelligent existences, the Creator, doubtless, intended that it should make a sublime and reverential impression on the minds of all the intellectual beings to whom it might be displayed, and that it should convey some *palpable* idea of the infinite glories of his nature, in so far as material objects can be supposed to adumbrate the perfections of a spiritual and uncreated Essence. Dwelling in light "inaccessible" to mortals, and forever vailed from the highest created being, by the pure spirituality and immensity of his nature, there is no conceivable mode by which the infinite grandeur of Deity could be exhibited to finite intelligences, but through the medium of those magnificent operations which are incessantly going forward throughout the boundless regions of space. Concealed from the gaze of all the "principalities and powers" in heaven, in the unfathomable depths of his Essence, he displays his presence in the universe he has created, and the glory of his power, by launching magnificent worlds into existence, by adorning them with diversified splendors, by peopling them with various ranks of intelligent existence, and by impelling them in their movements through the illimitable tracts of creation.

It will readily be admitted by every enlightened Christian, that it must be a highly desirable attainment, to acquire the most glorious idea of the Divine Being, which the limited capacity of our minds is capable of receiving. This is one of the grand difficulties in religion. The idea of a Being purely IMMATERIAL, yet pervading infinite space, and possessed of no sensible qualities, confounds and bewilders the human intellect, so that its conceptions, on the one hand, are apt to verge toward extravagancy, while, on the other, they are apt to degenerate into something approaching to inanity. Mere abstract ideas and reasonings respecting infinity, eternity, and absolute perfection, however sublime we may conceive them to be, completely fail in arresting the understanding, and affecting the heart; our conceptions become vague, empty, and confused, for want of a material vehicle to give them order, stability, and expansion. Something of the nature of vast extension, of splendid and variegated objects, and of mighty movements, is absolutely necessary, in order to convey to spirits dwelling in bodies of clay, a definite conception of the invisible glories of the Eternal Mind; and, therefore, in the immense variety of material existence with which the universe is adorned, we find every requisite assistance of this kind to direct and expand our views of the Great Object of our adoration. When the mind is perplexed and overwhelmed with its conceptions, when it labors, as it were, to form some well defined conceptions of an Infinite Being, it here finds some tangible objects on which to fix, some sensible *substratum* for its thoughts to rest upon for a little, while it attempts to penetrate, in its excursions, into those distant regions which eye hath not seen, and to connect the whole of its mental survey with the energies of the "King Eternal, Immortal, and Invisible."

---

[*] Isaiah xlvi. 11.

[†] Romans i. 20.

[‡] Ridgely's Body of Divinity, p. 39.

To such a train of thought we are uniformly directed in the Sacred Oracles, where Jehovah is represented as describing himself by the *effects* which his power and wisdom have produced:—"Israel shall be saved in the Lord with an everlasting salvation. For thus saith Jehovah that created the heavens; God himself that formed the earth and made it; he hath established it, he created it not in vain, he formed it to be inhabited; I am the Lord, and there is none else." "I have made the earth and created man upon it, my hands have stretched out the heavens, and all their hosts have I commanded. Hearken unto me, O Israel: I am the first, I also am the last. Mine hand also hath laid the foundation of the earth, and my right hand hath spanned the heavens; when I call unto them, they stand up together. Who hath measured the waters in the hollow of his hand, and meted out heaven with a span, and weighed the mountains in scales? He who sitteth upon the circle of the earth, and the inhabitants thereof are as grasshoppers; that stretcheth out the heavens as a curtain, that fainteth not, neither is weary." "The Lord made the heavens, the heaven of heavens, with all their hosts; honor and majesty are before him, and his kingdom ruleth over all." *—Such sublime descriptions of Jehovah, and references to his material works, are reiterated in every portion of the sacred volume: and the import and sublimity of such expressions cannot be fully appreciated, unless we take into view all the magnificent objects which science has unvailed in the distant regions of creation.

This subject is calculated, not merely to overpower the intellect with an idea of sublimity and grandeur, but also to produce deep *moral* impressions upon the heart; and a Christian philosopher would be deficient in his duty were he to overlook this tendency of the objects of his contemplation.

One important moral effect which this subject has a natural tendency to produce, is, profound HUMILITY. What an insignificant being does man appear, when he compares himself with the magnificence of creation, and with the myriads of exalted intelligences with which it is peopled! What are all the honors and splendors of this earthly ball, of which mortals are so proud, when placed in competition with the resplendent glories of the skies! Such a display as the Almighty has given of himself, in the magnitude and variety of his works, was evidently intended "to stain the pride" of all human grandeur, that "no flesh should glory in his presence." Yet there is no disposition that appears so prominent among puny mortals as pride, ambition, and vain-glory—the very opposite of humility, and of all those tempers which become those "who dwell in tabernacles of clay, and whose foundation is in the dust." Even without taking into account the state of man as a *depraved* intelligence, what is there in his situation that should inspire him with "lofty looks," and induce him to look down on his fellow-men with supercilious contempt? He derived his origin from the dust, he is allied to the beasts that perish, and he is fast hastening to the grave, where his carcass will become the food of noisome reptiles. He is every moment dependent on a Superior Being for every pulse that beats, and every breath he draws, and for all that he possesses; he is dependent even on the meanest of his species for his accommodations and comforts. He holds every enjoyment on the most precarious tenure,—his friends may be snatched in a moment from his embrace; his riches may take to themselves wings and fly away; and his health and beauty may be blasted in an hour, by a breath of wind. Hunger and thirst, cold and heat, poverty and disgrace, sorrow and disappointment, pain and disease, mingle themselves with all his pursuits and enjoyments. His knowledge is circumscribed within the narrowest limits, his errors and follies are glaring and innumerable; and he stands as an almost undistinguishable atom, amidst the immensity of God's works. Still, with all these powerful inducements to the exercise of humility, man dares to be proud and arrogant:

> "Man, proud man,
> Dress'd in a little brief authority,
> Plays such fantastic tricks before high heaven,
> As make the angels weep."

How affecting to contemplate the warrior, flushed with diabolical pride, pursuing his conquests through heaps of slain, in order to obtain possession of "a poor pitiable speck of perishing earth;" exclaiming in his rage, "I will pursue, I will overtake, I will divide the spoil, my lust shall be satisfied upon them, I will draw the sword, my hand shall destroy them"—to behold the man of rank glorying in his wealth, and his empty titles, and looking around upon the inferior orders of his fellow-mortals as the worms of the dust—to behold the man of ambition pushing his way through bribery, and treachery, and slaughter, to gain possession of a throne, that he may look down with proud pre-eminence upon his fellows—to behold the haughty airs of the noble dame, inflated with the idea of her beauty, and her high birth, as she struts along, surveying the ignoble crowd, as if they were the dust beneath her feet—to behold the smatterer in learning, puffed up with a vain conceit of his superficial acquirements, when he has scarcely entered the porch of knowledge,—in fine, to behold all ranks, from the highest to the lowest, big with an idea of their own importance, and fired with pride and revenge at the least provocation, whether imaginary or real! How inconsistent the manifestations of such tempers, with the many humiliating circumstances of our present condition, and with the low rank which we hold in the scale of Universal Being.

It is not improbable, that there are in the universe, intelligences of a superior order, in whose breasts pride never found a place—to whom this globe of ours, and all its inhabitants, appear as inconsiderable as a drop of water, filled with microscopic animalcules, does to the proud lords of this earthly region. There is at least *one* Being to whom this sentiment is applicable, in its utmost extent:—"Before HIM all nations are as a drop of a bucket, and the inhabitants of the earth as grasshoppers; yea, they are as nothing, and are counted to him less than nothing and vanity" Could we wing our way with the swiftness of a seraph, from sun to sun, and from world to world, until we had surveyed all the systems visible to the naked eye, which are only as a mere speck in the map of the universe—could we, at the same time, contemplate the glorious landscapes and scenes of grandeur they exhibit—could we also mingle with the pure and exalted intelligences which people those resplendent abodes, and behold their humble and ardent adorations of their Almighty Maker, their benign and condescending deportment toward one another; "each esteeming another better than himself," and all united in the bonds of the purest affection, without one haughty or discordant feeling—what indignation and astonishment would seize us on our return to this obscure corner of creation, to behold beings enveloped in the mists of ignorance, immersed in depravity and wickedness, liable to a thousand accidents, exposed to the ravages of the earthquake, the volcano, and the storm; yet proud as Lucifer, and glorying in their shame! We should be apt to view them, as we now do those bedlamites, who fancy themselves to be kings, surrounded by their nobles, while they are chained to the walls of a noisome dungeon. "Sure pride was never made for man." How abhorrent, then, must it appear in the eyes of superior beings, who have taken an expansive range through the field of creation! How abhorrent it is in the sight of the Almighty, and how amiable is the opposite virtue, we learn from his word:—"Every one that is proud in heart is an abomination to the Lord."—"God resisteth the proud, but he giveth grace to the humble."—"Thus saith the High and Lofty One, who inhabiteth eternity, I dwell in the high and holy place; with him also that is of an humble and contrite spirit; to revive the spirit of the humble, and the heart of the contrite ones."—While, therefore, we contemplate the Omnipotence of God in the immensity of creation, let us learn to cultivate humility and self-abasement. This was one of the lessons which the pious Psalmist deduced from his survey of the nocturnal heavens. When he beheld the moon walking in brightness, and the innumerable host of stars—overpowered with a sense of his own insignificance, and the greatness of Divine condescension, he exclaimed, "O Lord! what is man, that thou art mindful of him, or the son of man, that thou shouldst visit him!"

---

* Isaiah xlv. 17, 18 12; xlviii. 12, 13; xl. 12, 22, etc.

Again, this subject is also calculated to inspire us with REVERENCE and VENERATION of God. Profound veneration of the Divine Being lies at the foundation of all religious worship and obedience. But, in order to reverence God aright, we must know him; and, in order to acquire the true knowledge of him, we must contemplate him through the medium of those works and dispensations, by which he displays the glories of his nature to the inhabitants of our world. I have already exhibited a few specimens of the stupendous operations of his power, in that portion of the system of the universe which lies open to our inspection; and there is, surely, no mind in which the least spark of piety exists, but must feel strong emotions of reverence and awe, at the thought of that Almighty and Incomprehensible Being, who impels the huge masses of the planetary globes with so amazing a rapidity through the sky, and who has diversified the voids of space with so vast an assemblage of magnificent worlds. Even those manifestations of Deity which are confined to the globe we inhabit, when attentively considered, are calculated to rouse, even the unthinking mind, to astonishment and awe. The lofty mountains, and expansive plains, the mass of waters in the mighty ocean, the thunders rolling along the sky, the lightnings flashing from cloud to cloud, the hurricane and the tempest, the volcano vomiting rivers of fire, and the earthquake shaking kingdoms, and leveling cities with the ground—all proclaim the Majesty of Him, by whom the elements of nature are arranged and directed, and seem to address the sons of men in language like this: "The Lord reigneth, he is clothed with majesty; at his wrath the earth trembles; a fire goeth before him, and burneth up his enemies."—"Let all the earth fear the Lord, let all the inhabitants of the world stand in awe of him."

There is one reason, among others, why the bulk of mankind feel so little veneration of God, and that is, that they seldom contemplate, with fixed attention, "the operations of his hands." If we wish to cherish this sublime sentiment in our hearts, we must familiarize our minds to frequent excursions over all those scenes of Creation and Providence, which the volume of nature, and the volume of inspiration, unfold to view. We must endeavor to assist our conceptions of the grandeur of these objects, by every discovery which has been, or may yet be made, and by every mode of illustration by which a sublime and comprehensive idea of the particular object of contemplation may be obtained.—If we would wish to acquire some definite, though imperfect conception of the physical extent of the universe, our minds might be assisted by such illustrations as the following:—Light flies from the sun with a velocity of nearly two hundred thousand miles in a moment of time, or about 1,400,000 times swifter than the motion of a cannon ball. Suppose that one of the highest order of intelligences is endowed with a power of rapid motion superior to that of light, and with a corresponding degree of intellectual energy; that he has been flying, without intermission, from one province of creation to another, for six thousand years, and will continue the same rapid course for a thousand millions of years to come; it is highly probable, if not absolutely certain, that at the end of this vast tour, he would have advanced no farther than "the suburbs of creation"—and that all the magnificent systems of material and intellectual beings he had surveyed during his rapid flight, and for such a length of ages, bear no more proportion to the whole Empire of Omnipotence, than the smallest grain of sand does to all the particles of matter of the same size contained in ten thousand worlds. Nor need we entertain the least fear, that the idea of the extent of the Creator's power, conveyed by such a representation, exceeds the bounds of reality. On the other hand, it must fall almost infinitely short of it. For, as the poet has justly observed—

"Can man *conceive* beyond what God can *do?*"

Were a seraph, in prosecuting the tour of creation in the manner now stated, ever to arrive at a limit beyond which no further displays of the Divinity could be perceived, the thought would overwhelm his faculties with unutterable anguish and horror; he would feel, that he had now, in some measure, comprehended all the plans and operations of Omnipotence, and that no further manifestations of the Divine glory remained to be explored. But we may rest assured, that this can never happen in the case of any created intelligence. We have every reason to believe, both from the nature of an Infinite Being, and from the vast extent of creation already explored, that the immense mass of material existence, and the endless variety of sensitive and intellectual beings with which the universe is replenished, are intended by Jehovah, to present to his rational offspring, a *shadow*, an *emblem*, or a *representation* (in so far as finite extended existence can be representation) of the *Infinite Perfections* of his nature, which would otherwise have remained forever impalpable to all subordinate intelligences.

In this manner, then, might we occasionally exercise our minds on the grand and diversified objects which the universe exhibits; and, in proportion as we enlarge the sphere of our contemplations, in a similar proportion will our views of God himself be extended, and a corresponding sentiment of veneration impressed upon the mind. For the soul of man cannot reverence a mere abstract being, that was never manifested through a sensible medium, however many lofty terms may be used to describe his perfections. It reverences that Ineffable being, who conceals himself behind the scenes of Creation, through the medium of the visible display he exhibits of his Power, Wisdom, and Beneficence, in the economy of Nature, and in the Records of Revelation.—Before the universe was formed, Jehovah existed alone, possessed of every attribute which he now displays. But, had only one solitary intelligence been created, and placed in the infinite void, without a material substratum beneath and around him, he could never have been animated with a sentiment of profound veneration for his Creator; because no objects existed to excite it, or to show that his Invisible Maker was invested with those attributes which he is now known to possess. Accordingly, we find in the sacred writings, that, when a sentiment of reverence is demanded from the sons of men, those sensible objects which are calculated to excite the emotion are uniformly exhibited. "Fear ye not me, saith the Lord? Will ye not tremble at my presence, who have placed the sand for the bound of the sea, by a perpetual decree, that it cannot pass it; and though the waves thereof toss themselves, yet they cannot prevail; though they roar, yet can they not pass over it?" "Who would not fear thee, O King of nations! Thou art the true God, and an everlasting King. Thou hast made the earth by thy power, thou hast established the world by thy wisdom, thou hast stretched out the heavens by thy discretion. When thou utterest thy voice there is a noise of waters in the heavens, thou causest the vapors to ascend from the ends of the earth, thou makest lightnings with rain, and bringest forth the winds out of thy treasuries." *

But however enlarged and venerable conceptions of God we may derive from the manifestations of his power, they must fall infinitely short of what is due to a being of boundless perfection. For there may be attributes in the Divine Essence of which we cannot possibly form the least conception—attributes which cannot be shadowed forth or represented by any portion of the material or intellectual world yet discovered by us, or by all the mighty achievements by which human redemption was effected—attributes which have not yet been displayed, in their effects, to the highest orders of intelligent existence. And therefore, as that excellent philosopher and divine, the honorable Mr. Boyle, has well observed, "Our ideas of God, however great, will rather express the greatness of our veneration than the immensity of his perfections; and the notions worthy the most intelligent men are far short of being worthy the incomprehensible God—the brightest idea we can frame of God being infinitely inferior, and no more than a *Parhelion* † in respect of the sun; for though that meteor is splendid, and resembles the sun, yet it resides in a cloud, and is not only much beneath the sun in distance, but inferior in bigness and splendor."

In short, were we habitually to cherish that profound veneration of God which his works are calculated to inspire, with what humility would we approach the presence of this August Being! with what emotions of awe would we present our adorations! and with what reverence would we talk of his inscrutable purposes and incomprehensible operations! We would not talk about him as some writers have done, with the same ease and indifference as a mathematician would talk about the properties of a triangle, or a philosopher about the effects of a mechanical engine; nor would we treat with a spirit of levity any of the solemn declarations of his word, or the mighty movements of his providence. We would be ever ready to join with ardor in the sublime devotions of the inspired writers, "Great and marvelous are thy works, Lord God Almighty, just and true are thy ways, thou King of saints! Who would not fear thee, O Lord, and glorify thy name? Let all the earth fear the Lord, let all the inhabitants of the world stand in awe of him."

Lastly, The views we have taken of the omnipotence and grandeur of the Deity are calculated to inspire us with HOPE and CONFIDENCE in the prospect of that eternal existence which lies before us. The period of our existence in this terrestrial scene will soon terminate, and those bodies, through which we now hold a correspondence with the visible creation, crumble into dust. The gradual decay, and the ultimate dissolution of human bodies, present a scene at which reason stands aghast; and, on a cursory survey of the chambers of the dead, it is apt to exclaim, in the language of despair, "Can these dry bones live?" A thousand difficulties crowd upon the mind which appear repugnant to the idea, that beauty shall again spring out of ashes, and life out of the dust. But, when we look abroad to the displays of Divine power and intelligence, in the wide expanse of Creation, we perceive that

> "Almighty God
> Has done much more; nor is his arm impair'd
> Through length of days.—And what he can, he will;
> His faithfulness stands bound to see it done."—BLAIR.

We perceive that he has created systems in such vast profusion that no man can number them. The worlds every moment under his superintendence and direction are unquestionably far more numerous than all the human beings who have hitherto existed, or will yet exist until the close of time. And if he has not only arranged the general features of each of these worlds, and established the physical laws by which its economy is regulated, but has also arranged the diversified circumstances, and directs the minutest movements of the myriads of sensitive and intellectual existences it contains, we ought never for a moment to doubt that the minutest particles of every human body, however widely separated from each other, and mingled with other extraneous substances, are known to Him whose presence pervades all space; and that all the atoms requisite for the construction of the Resurrection-body will be reassembled for this purpose "by the energy of that mighty power whereby he is able to subdue all things to himself." If we suppose that a number of human beings, amounting to three hundred thousand millions, shall start from the grave into new life at the general resurrection, and that the atoms of each of these bodies are just now under the special superintendence of the Almighty—and that, at least, an equal number of worlds are under his particular care and direction—the exertion of power and intelligence, in the former case, cannot be supposed to be greater than what is requisite in the latter. To a Being possessed of Infinite Power, conjoined with Boundless Intelligence, the superintendence of countless atoms, and of countless worlds, is equally easy, where no contradiction is implied. For, as the poet has well observed,—

---

* Jeremiah x. 7-13.

† A *Parhelion*, or *Mock-Sun*, is a meteor in the form of a very bright light appearing on one side of the sun, and somewhat resembling the appearance of that luminary. This phenomenon is supposed to be produced by the refraction and reflection of the sun's rays from a watery cloud. Sometimes three or four of these parhelia, all of them bearing a certain resemblance to the real sun, have been seen at one time.

> "He summons into being with like ease
> A whole creation and a single grain."

And since this subject tends to strengthen our hope of a resurrection from the dead, it is also calculated to inspire us with confidence in the prospect of those eternal scenes which will burst upon the view, at the dissolution of all terrestrial things. Beyond the period fixed for the conflagration of this world, "a wide and unbounded prospect lies before us:" and though, at present, "shadows, clouds, and darkness rest upon it," yet the boundless magnificence of the Divine empire which science has unfolded, throws a radiance over the scenes of futurity, which is fraught with consolation, in the view of "the wreck of matter and the crash of worlds." It opens to us a prospect of perpetual improvement in knowledge and felicity; it presents a field in which the human faculties may be forever expanding, forever contemplating new scenes of grandeur rising to the view, in boundless perspective, through an interminable succession of existence. It convinces us, that the happiness of the eternal state will not consist in an unvaried repetition of the same perceptions and enjoyments, but that new displays of the Creator's glory will be continually bursting on the astonished mind, world without end. And as we know that the same beneficence and care which are displayed in the arrangements of systems of worlds, are also displayed in supporting and providing for the smallest microscopic animalcule, we have no reason to harbor the least fear lest we should be overlooked in the immensity of creation, or lost amidst the multiplicity of those works among which the Deity is incessantly employed: For, as he is *Omnipresent*, his essence pervades, actuates, and supports the whole frame of universal nature, and all the beings it contains, so that he is as intimately present with every created being, whether sensitive or intellectual, as that being is to itself. And as he is *Omniscient*, he is conscious of every movement that can arise in the material system, and of every thought and purpose that can pervade the world of intellectual existence,—and consequently his superintendence and care must extend to every creature he has formed. Therefore, though the "elements shall melt with fervent heat, and the earth and all the works therein be dissolved, yet we, according to his promise, look for new heavens and a new earth, wherein dwelleth righteousness."

SECTION III.

ON THE WISDOM AND INTELLIGENCE OF THE DEITY.

In surveying the system of nature with a Christian and a philosophic eye, it may be considered in different points of view. It may be viewed either as displaying the power and magnificence of the Deity in the immense quantity of materials of which it is composed, and in the august machinery and movements by which its economy is directed;—or, as manifesting his Wisdom in the nice adaptation of every minute circumstance to the end it was intended to accomplish;—or, as illustrating his unbounded beneficence in the provision which is made for the accommodation and happiness of the numerous tribes of sentient and intelligent beings it contains. Having, in the preceding section, endeavored to exhibit some of those objects which evince the Omnipotence of Deity, and the pious emotions they are calculated to excite, I shall now offer a few popular illustrations of Divine Wisdom, as displayed in the arrangements of the material world—which shall chiefly be confined to those objects which are most prominent and obvious to the vulgar eye.

Wisdom is that perfection of an intelligent agent, by which he is enabled to select and employ the most proper means in order to accomplish a good and important end. It includes the idea of knowledge or intelligence, but may be distinguished from it. Knowledge is opposed to ignorance, Wisdom is opposed to folly or error in conduct. As applied to God, it may be considered as comprehending the operations of his Omniscience and Benevolence; or, in other words, his knowledge to discern, and his disposition to choose those means and ends which are calculated to promote the order and the happiness of the universe.

The Wisdom of God is, doubtless, displayed in every arrangement he has made throughout all the provinces of his immense and eternal kingdom, however far they may be removed from the sphere of human observation. But it is only in those parts of the system of nature which lie open to our particular investigation, that the traces of this perfection can be distinctly perceived. The *heavens* declare the glory of God's Wisdom, as well as of his Power. The planetary system—that portion of the heavens with which we are best acquainted—displays both the magnificence and the skill of its Divine Author,—in the magnitudes, distances, revolutions, proportions, and uses of the various globes of which it is composed, and in the diversified apparatus by which light and darkness are alternately distributed. The sun, an immense luminous world, by far the largest body in the system, is placed in the center. No other position would have suited for an equable distribution of illumination and heat through the different parts of the system. Around him, at different distances, eleven primary planets revolve, accompanied with eighteen secondaries or moons,—all in majestic order and harmony, no one interrupting the movements of another, but invariably keeping the paths prescribed them, and performing their revolutions in their appointed times. To all these revolving globes, the sun dispenses motion, light, heat, fertility, and other unceasing energies, for the comfort and happiness of their respective inhabitants—without which, perpetual sterility, eternal winter, and eternal night, would reign over every region of our globe, and throughout surrounding worlds.

The distance at which the heavenly bodies, particularly the sun, are placed from the earth, is a manifest evidence of Divine Wisdom. If the sun were much nearer us than he is at present, the earth, as now constituted, would be wasted and parched with excessive heat; the waters would be turned into vapor, and the rivers, seas, and oceans, would soon disappear, leaving nothing behind them but frightful barren dells and gloomy caverns; vegetation would completely cease, and the tribes of animated nature languish and die. On the other hand, were the sun much farther distant than he now is, or were his bulk, or the influence of his rays diminished one half of what they now are, the land and the ocean would soon become one frozen mass, and universal desolation and sterility would overspread the fair face of nature; and instead of a pleasant and comfortable abode, our globe would become a frightful desert, a state of misery and perpetual punishment.[*] But herein is the wisdom of God displayed, that he has formed the sun of such a determinate size, and placed it at such a convenient distance, as not to annoy, but to refresh and cheer us, and to enliven the soil with its genial influence; so that we plainly perceive, to use the language of the prophet, that "He hath established the world by his wisdom, and stretched out the heavens by his understanding."

The rotation of the several planetary globes around their axes, to produce the alternate succession of day and night, strikingly demonstrates the wisdom and benevolence of their great Author. Were the earth and the other planetary worlds destitute of a diurnal motion, only one-half of their surfaces could be inhabited, and the other half would remain a dark and cheerless desert. The sun would be the only heavenly orb which would be recognized by the inhabitants of each respective world, as existing in the universe, and that scene of grandeur which night unfolds in the boundless expanse of the sky would be forever vailed from their view. For, it appears to be one grand design of the Creator, in giving these bodies a diurnal motion, not only to cheer their inhabitants with light and warmth, and the gay coloring produced by the solar rays; but also to open to them a prospect of other portions of his vast dominions, which are dispersed in endless variety throughout the illimitable regions of space, in order that they may acquire a more sublime impression of the glory of his kingdom, and of his eternal Power and Godhead. But were perpetual day to irradiate the planets, it would throw an eternal and impenetrable vail over the glories of the sky, behind which the magnificent operations of Jehovah's power would be in a great measure concealed. It is this circumstance which we should consider as the principal reason why a rotatory motion has been impressed on the planetary globes; and not merely that a curtain of darkness might be thrown around their inhabitants during the repose of sleep, as in the world in which we dwell. For, in some of the other planetary worlds belonging to our system, the intelligent beings with which they are peopled may stand in no need of that nocturnal repose which is necessary for man; their physical powers may be incapable of being impaired, and their mental energies may be in perpetual exercise. And in some of those bodies which are surrounded with an assemblage of rings and moons, as the planet Saturn, the diversified grandeur of their celestial phenomena, in the absence of the sun, may present a scene of contemplation and enjoyment far more interesting than all the splendors of their noon-day. Beside, had the planets no motion round their axes, and were both their hemispheres supposed to be peopled with inhabitants, their physical state and enjoyments would be as opposite to each other, as if they lived under the government of two distinct independent beings. While the one class was basking under the splendors of perpetual day, the other would be involved in all the horrors of an everlasting night. While the one hemisphere would be parched with excessive heat, the other would be bound in the fetters of eternal ice; and in such a globe as ours, the motion of the tides, the ascent of the vapors, the currents of the atmosphere, the course of the winds, the benign influences of the rains and dews, and a thousand other movements, which produce so many salutary and beneficial effects, would be completely deranged. Hence we find, that in all the planetary bodies on which spots have been discovered, a rotatory motion actually exists,[*] in the secondary as well as in the primary planets, and even in the sun itself, the center and the mover of the whole: in which arrangement of the Almighty Creator, the evidences of wisdom and design are strikingly apparent.

This amazing scene of Divine workmanship and skill which the planetary system exhibits, we have reason to believe is multiplied and diversified to an indefinite extent, throughout all the other systems of creation, displaying to the intelligences of every region "the manifold wisdom of God." For there can be no question, that every star we now behold, either by the naked eye or by the help of a telescope, is the center of a system of planetary worlds, where the agency of God, and his unsearchable wisdom, may be endlessly varied, and perhaps more strikingly displayed than even in the system to which we belong. These vast globes of light could never have been designed merely to shed a few glimmering rays on our far distant world: for the ten thousandth part of them has never yet been seen by the inhabitants of the earth since the Mosaic creation, except by a few astronomers of the past and the present age; and the light of many of them, in all probability, has never yet reached us, and perhaps never will until the period of "the consummation of all terrestrial things." They were not made in vain; for such a supposition would be inconsistent with every idea we can form of the attributes of a Being of infinite perfection. They were not intended merely to diversify the voids of infinite space with a useless splendor which has no relation to intellectual natures: for this would give us a most distorted and inconsistent idea of the character of Him who is "the only-wise God;" and we are told by an authority which cannot be questioned, that "by his wisdom he made the heavens, and stretched them out by his understanding." The only rational conclusion, therefore, which can be deduced, is, that they are destined to distribute illumination and splendor, vivifying influence and happiness, among incalculable numbers of intelligent beings, of various degrees of physical, moral, and intellectual excellence. And wherever the Creator has exerted his Almighty energies in the production of sensitive and intellectual natures we may rest assured, that there also his infinite wisdom and intelligence, in an endless variety of arrangements, contrivances, and adaptations, are unceasingly displayed.

---

[*] It forms no objection to these remarks, that *caloric*, or the matter of *heat*, does not altogether depend upon the direct influence of the solar rays. The substance of caloric may be chiefly connected with the constitution of the globe we inhabit. But still it is quite certain, that the earth, *as presently constituted*, would suffer effects most disastrous to sentient beings, were it removed much nearer to, or much farther from the central luminary. Those planets which are removed several hundreds of millions of miles farther from the sun than our globe, may possibly experience a degree of heat much greater than ours; but, in this case the constitution of the solid parts of these globes, and of their surrounding atmospheres, must be very different from what obtains in the physical arrangements of our globe.

[*] On the planet *Uranus*, or Herschel, no spots or inequalities of surface have been discovered, on account of its great distance from the earth; but spots have been discovered on the planets Saturn, Jupiter, Mars, and Venus, by which their diurnal rotations have been ascertained. There can be no doubt, however, that Uranus rotates on an axis as well as the other planets, although its distance prevents us from determining this point by actual observation.

But, after all, whatever evidences of contrivance and design the celestial globes may exhibit, it is not in the heavens that the most striking displays of Divine *wisdom* can be traced by the inhabitants of our world. It is only a few *general relations* and adaptations that can be distinctly perceived among the orbs of the firmament; though, in so far as we are able to trace the purposes which they subserve, the marks of beauty, order, and design, are uniformly apparent. But we are placed at too great a distance from the orbs of heaven, to be able to investigate the particular arrangements which enter into the physical and moral economy of the celestial worlds. Were we transported to the surface of the planet Jupiter, and had an opportunity of surveying, at leisure, the regions of that vast globe, and the tribes of sensitive and intellectual existence which compose its population — of contemplating the relations of its moons to the pleasure and comfort of its inhabitants — the constitution of its atmosphere as to its reflective and refractive powers, in producing a degree of illumination to compensate for the great distance of that planet from the sun —its adaptation to the functions of animal life— the construction of the visual organs of its inhabitants, and the degree of sensibility they possess, corresponding to the quantity of light received from the sun—the temperature of the surface and atmosphere of this globe, corresponding to its distance from the central source of heat, and to the physical constitution of sensitive beings — in short, could we investigate the relations which inanimate nature, in all its varieties and sublimities, bears to the necessities and the happiness of the animated existences that traverse its different regions, we should, doubtless, behold a scene of Divine wisdom and intelligence, far more admirable and astonishing than even that which is exhibited in our sublunary world.—But since it is impossible for us to investigate the economy of other worlds, while we are chained down to this terrestrial sphere, we must direct our attention to those arrangements and contrivances in the constitution of our own globe, which lie open to our particular inspection, in order to perceive more distinctly the benevolent designs of Him "in whom we live, and move, and have our being." And here an attentive observer will find, in almost every object, when minutely examined, a display of goodness and intelligence, which will constrain him to exclaim, "O the depth of the riches, both of the wisdom and the knowledge of God!"

Wisdom, considered as consisting in contrivance, or the selection of the most proper means in order to accomplish an important end, may be exemplified and illustrated in a variety of familiar objects in the scene of nature.

The *earth* on which we tread was evidently intended by the Creator to support man and other animals, along with their habitations, and to furnish those vegetable productions which are necessary for their subsistence; and, accordingly, he has given it that exact degree of consistency which is requisite for these purposes. Were it much harder than it now is—were it, for example, as dense as a rock, it would be incapable of cultivation, and vegetables could not be produced from its surface. Were it softer it would be insufficient to support us, and we should sink at every step, like a person walking in a quagmire. No buildings, such as those we now construct could have been supported, and no conveyances such as coaches and steam-carriages could have moved along its surface. Had this circumstance not been attended to in its formation, the earth would have been rendered useless as a habitable world for all those animated beings which now traverse its different regions. The exact adjustments of the solid parts of the globe to the nature and necessities of the beings which inhabit it, is therefore an instance and an evidence of *wisdom.*

The *diversity of surface* which it everywhere presents, in the mountains and vales with which it is variegated, indicates the same benevolent contrivance and design. If the earth were divested of its mountains, and its surface were everywhere uniformly smooth, there would be no rivers, springs, or fountains; for water can flow only from a higher to a lower place; the vegetable tribes would droop and languish; man and other animals would be deprived of what is necessary for their existence and comfort; we should be destitute of many useful stones, minerals, plants, and trees, which are now produced on the surface and in the interior of mountains; the sea itself would become a stagnant marsh, or overflow the land; and the whole surface of nature in our terrestrial sphere would present an unvaried scene of dull uniformity. Those picturesque and sublime scenes which fire the imagination of the poet, and which render mountainous districts so pleasing to the philosophic traveler, would be completely withdrawn; and all around, when compared with such diversified landscapes, would appear as fatiguing to the eye as the vast solitudes of the Arabian deserts, or the dull monotony of the ocean. But, in consequence of the admirable distribution of hills and mountains over the surface of our globe, a variety of useful and ornamental effects is produced. Their lofty summits are destined by Providence to arrest the vapors which float in the regions of the air; their internal cavities form so many spacious basins for the reception of water distilled from the clouds; they are the original sources of springs and rivers, which water and fertilize the earth; they form immense magazines, in which are deposited stones, metals, and minerals, which are of so essential service in the arts that promote the comfort of human life; they serve for the production of a vast variety of herbs and trees; they arrest the progress of storms and tempests; they afford shelter and entertainment to various animals which minister to the wants of mankind: in a word, they adorn and embellish the face of nature—they form thousands of sublime and beautiful landscapes, and afford from their summits the most delightful prospects of the plains below. All these circumstances demonstrate the consummate wisdom of the Great Architect of nature, and lead us to conclude, that mountains, so far from being rude excrescences of nature, as some have asserted, form an essential part of the constitution, not only of our globe, but of all habitable worlds.—And this conclusion is confirmed, so far as our observation extends, with regard to the moon, and several of the planetary bodies which belong to our system, whose surfaces are found to be diversified by sublime ramifications of mountain scenery; which circumstance forms one collateral proof, among many others, that they are the abodes of sentient and intellectual beings.

Again, the *coloring* which is spread over the face of nature indicates the wisdom of the Deity. It is essential to the present mode of our existence, and it was evidently intended by the Creator, that we should be enabled easily to recognize the forms and properties of the various objects with which we are surrounded. But were the objects of nature destitute of color, or were the same unvaried hue spread over the face of creation, we should be destitute of all the entertainments of vision, and be at a loss to distinguish one object from another. We should be unable to distinguish rugged precipices from fruitful hills—naked rocks from human habitations—the trees from the hills that bear them—and the tilled from the untilled lands. "We should hesitate to pronounce whether an adjacent inclosure contains a piece of pasturage, a plot of arable land, or a field of corn; and it would require a little journey, and a minute investigation, to determine such a point. We could not determine whether the first person we met were a soldier in his regimentals, or a swain in his Sunday suit; a bride in her ornaments, or a widow in her weeds." Such would have been the aspect of nature, and such the inconveniences to which we should have been subjected, had God allowed us light, without the distinction of colors. We could have distinguished objects only by intricate trains of reasoning, and by circumstances of time, place, and relative position. And to what delays and perplexities should we have been reduced, had we been obliged every moment to distinguish one thing from another by reasoning? Our whole life must then have been employed rather in study than in action; and after all, we must have remained in eternal uncertainty as to many things which are now quite obvious to every one as soon as he opens his eyes. We could neither have communicated our thoughts by writing, nor have derived instruction from others through the medium of books; for it is the contrast of different colors which enables us to distinguish the letters, words, and sentences, in a written or printed book—so that we should now have been almost as ignorant of the transactions of past ages, as we are of the events which are passing in the planetary worlds; and, consequently, we could never have enjoyed a written revelation from Heaven, nor any other infallible guide to direct us in the path to happiness, if the Almighty had not distinguished the rays of light, and painted the objects around us with a diversity of colors,—so essentially connected are the minutest and the most magnificent works of Deity. But now, in the present constitution of things, color characterizes the class to which every individual belongs, and indicates, upon the first inspection, its respective quality. Every object wears its peculiar livery, and has a distinguishing mark by which it is characterized.

The different hues which are spread over the scenery of the world are also highly ornamental to the face of nature, and afford a variety of pleasures to the eye and the imagination. It is this circumstance which adds a charm to the fields, the valleys, and the hills, the lofty mountain, the winding river, and the expansive lake; and which gives a splendor and sublimity to the capacious vault of heaven. Color is therefore an essential requisite to every world inhabited by sensitive beings; and we know, that provision has been made for diffusing it throughout all the globes which may exist in the distant regions which our telescopes have penetrated; for the light which radiates from the most distant stars is capable of being separated into the prismatic colors, similar to those which are produced by the solar rays; which furnishes a presumptive proof, that they are intended to accomplish designs, in their respective spheres, analogous to those which light subserves in our terrestrial habitation,—or, in other words, that they are destined to convey to the minds of sentient beings, impressions of light and color; and consequently, beings susceptible of such impressions must reside within the sphere or more immediate influence of these far distant orbs.

The same benevolent design is apparent in the *general color which prevails throughout the scene of sublunary nature.* Had the fields been clothed with hues of a deep red, or a brilliant white, the eye would have been dazzled with the splendor of their aspect. Had a dark blue or a black color generally prevailed, it would have cast a universal gloom over the face of nature. But an agreeable *green* holds the medium between these two extremes, equally remote from a dismal gloom and excessive splendor, and bears such a relation to the structure of the eye, that it refreshes instead of tiring it, and supports instead of diminishing its force. At the same time, though one general color prevails over the landscape of the earth, it is diversified by an admirable variety of shades, so that every individual object in the vegetable world can be accurately distinguished from another; thus producing a beautiful and variegated appearance over the whole scenery of nature.—"Who sees not, in all these things, that the hand of the Lord hath wrought this?"

If from the earth we turn our attention to the *waters*, we shall perceive similar traces of the exquisite wisdom and skill of the Author of nature. Water is one of the most essential elementary parts in the constitution of our globe, without which the various tribes of beings which now people it could not exist. It supplies a necessary beverage to man, and to all the animals that people the earth and the air. It forms a solvent for a great variety of solid bodies; it is the element in which an infinitude of organized beings pass their existence; it acts an important part in conveying life and nourishment to all the tribes of the vegetable kingdom, and gives salubrity to the atmospherical regions. Collected in immense masses in the basins of the sea, it serves as a vehicle for ships, and as a medium of communication between people of the most distant lands.—Carried along with a progressive motion over the beds of streams and of rivers, it gives a brisk impulse to the air, and prevents the unwholesome stagnation of vapors; it receives the filth of populous cities, and rids them of a thousand nuisances. By its impulsion, it becomes the mover of a multitude of machines; and, when rarified into steam, it is transformed into one of the most powerful and useful agents under the dominion of man.—All which beneficial effects entirely depend on the exact degree of density, or specific gravity, which the Creator has given to its constituent parts. Had it been much more rarified than it is, it would have been altogether unfit to answer the purposes now specified; the whole face of the earth would have been a dry and barren waste; vegetable nature could not have been nourished; our floating edifices could not have been supported; the lightest bodies would have sunk, and all regular intercourse with distant nations would have been prevented. On the other hand, had its parts been much denser than they are,—for example, had they been of the consistency of a thin jelly, similar disastrous effects would have inevitably followed; no ships could have plowed the ocean — no refreshing beverage would have been supplied to the animal tribes—the absorbent vessels of trees, herbs, and flowers, would have been unable to imbibe the moisture requisite for their nourishment, and we should thus have been deprived of all the beneficial effects we now derive from the use of that liquid element, and of all the diversified scenery of the vegetable world. But the configuration and consistency of its parts are so nicely adjusted to the constitution of the other elements, and to the wants of the sensitive and vegetable tribes, as exactly to subserve the ends intended in the system of nature.

Water has been ascertained to be a compound body, formed by the union of two different kinds of air—oxygen and hydrogen. It has the property of becoming, in certain cases, much lighter than air; though, in its natural liquid state, it is 800 times heavier than that fluid; and has also the property of afterward resuming its natural weight. Were it not for this property, evaporation could not be produced; and, consequently, no clouds, rain, nor dew could be formed, to water and fertilize the different regions of the earth. But in consequence of this wonderful property, the ocean becomes an inexhaustible cistern to our world. From its expansive surface are exhaled those vapors which supply the rivers and nourish the vegetable productions of every land. "The air and the sun," says an elegant writer, "constitute the mighty engine which works without intermission to raise the liquid treasure; while the clouds serve as so many aqueducts to convey them along the atmosphere, and distribute them at seasonable periods, and in regular proportions, through all the regions of the globe."

Notwithstanding the properties now stated, *motion was still requisite*, to insure all the advantages we now derive from the liquid element. Had the whole mass of waters been in a stagnant state, a thousand inconveniences and disastrous consequences would have inevitably ensued. But the All-wise Creator has impressed upon its various masses a circulating motion, which preserves its purity and widely extends its beneficial influence. The rills pour their liquid stores into the rivers; the rivers roll their watery treasures into the ocean; the waters of the ocean, by a libratory motion, roll backward and forward every twelve hours, and by means of currents and the force of winds, are kept in constant agitation. By the solar heat, a portion of these waters is carried up into the atmosphere, and, in the form of clouds, is conveyed by the winds over various regions; until at last it descends in rain and dew, to supply the springs "which run among the hills." So that there is a constant motion and circulation of the watery element, that it may serve as an agent for carrying forward the various processes of nature, and for ministering to the wants of man and beast.

In fine, were the waters in a state of perpetual stagnation, the filth of populous cities would be accumulated to a most unwholesome degree; the air would be filled with putrid exhalations, and the vegetable tribes would languish and die. Were they deprived of the property of being evaporated (in which state they occupy a space 1600 times greater than in their liquid state), rain and dew could never be produced, and the earth would be turned into "a dry and parched wilderness;" neither grass nor corn could be sufficiently dried to lay up for use; *our clothes, when washed, could never be dried;* and a variety of common operations which now conduce to our convenience and comfort, could never be carried on. But the infinite wisdom of the Creator, foreseeing all the effects which can possibly arise from these principles of nature, has effectually provided against such disasters, by arranging all things in number, weight, and measure, to subserve the beneficial ends for which they were ordained. "He causeth the vapors to ascend from the ends of the earth;" "he sendeth the springs into the valleys, which run among the hills. They give drink to every beast of the field; the wild asses quench their thirst. By them the fowls of heaven have their habitation, which sing among the branches. He watereth the hills from his chambers: the earth is satisfied with the fruit of his works.'

Let us now attend to the *atmosphere*, in the constitution of which the wisdom of God is no less conspicuous than in the other departments of nature.

The atmosphere is one of the most essential appendages of the globe we inhabit, and exhibits a most striking scene of Divine skill and omnipotence. The term *atmosphere* is applied to the whole mass of fluids, consisting of air, vapors, electric fluid, and other matters, which surround the earth to a certain hight. This mass of fluid matter gravitates to the earth, revolves with it in its diurnal rotation, and is carried along with it in its course round the sun every year. It has been computed to extend about 45 miles above the earth's surface, and it presses on the earth with a force proportioned to its hight and density. From experiments made by the barometer, it has been ascertained that it presses with a weight of about 15 pounds on every square inch of the earth's surface; and, therefore, its pressure on the body of a middle-sized man is equal to about 32,000 pounds, or 14 tons avoirdupois, a pressure which would be insupportable, and even fatal, were it not equal in every part, and counterbalanced by the spring of the air within us. The pressure of the whole atmosphere upon the earth is computed to be equivalent to that of a globe of lead 60 miles in diameter, or about 5,000,000,000,-000,000 tons; that is, the whole mass of air which surrounds the globe compresses the earth with a force or power equal to that of *five thousand millions of millions of tons.** This amazing pressure is, however, essentially necessary for the preservation of the present constitution of our globe, and of the animated beings which dwell on its surface. It prevents the heat of the sun from converting water, and all other fluids on the face of the earth, into vapor; and preserves the vessels of all organized beings in due tone and vigor. Were the atmospherical pressure entirely removed, the elastic fluids contained in the finer vessels of men and other animals, would inevitably burst them, and life would become extinct;†

---

* See Appendix, Note II.

† The necessity of the atmospherical pressure, for the comfort and preservation of animal life, might be illustrated by the effects experienced by those who have ascended to the summits of very high mountains, or who have been carried to a great hight above the surface of the earth in balloons. Acosta, in his relation of a journey among the mountains of Perü, states that "he and his companions were surprised with such extreme pangs of straining and vomiting, not without casting up of blood too, and with so violent a distemper, that they would undoubtedly have died had they remained two or three hours longer in that elevated situation." Count Zambeccari and his companions, who ascended in a balloon on the 7th of November, 1783, to a great height, found their hands and feet so swelled, that it was necessary for a surgeon to make incisions in the skin. In both the cases now stated, the persons ascended to so great a height that the pressure of the atmosphere was not sufficient to counterbalance the pressure of the fluids of the body.

and most of the substances on the face of the earth, particularly liquids, would be dissipated into vapor.

The atmosphere is now ascertained to be a compound substance, formed of two very different ingredients, termed *oxygen gas* and *nitrogen gas*. Of 100 measures of atmospheric air, 21 are oxygen, and 79 nitrogen. The one, namely, oxygen, is the principle of combustion and the vehicle of heat, and is absolutely necessary for the support of animal life, and is the most powerful and energetic agent in nature; the other is altogether incapable of supporting either flame or animal life. Were we to breathe oxygen air, without any mixture or alloy, our animal spirits would be raised, and the fluids in our bodies would circulate with greater rapidity; but we would soon infallibly perish by the rapid and unnatural accumulation of heat in the animal frame. If the nitrogen were extracted from the air, and the whole atmosphere contained nothing but oxygen or vital air, combustion would not proceed in that gradual manner which it now does, but with the most dreadful and irresistible rapidity: not only wood and coals, and other substances now used for fuel, but even stones, iron, and other metallic substances, would blaze with a rapidity which would carry destruction through the whole expanse of nature. If even the proportions of the two airs were materially altered, a variety of pernicious effects would instantly be produced. If the oxygen were less in quantity than it now is, fire would lose its strength, candles would not diffuse a sufficient light, and animals would perform their vital functions with the utmost difficulty and pain. On the other hand, were the nitrogen diminished and the oxygen increased, the air taken in by respiration would be more stimulant, and the circulation of the animal fluids would become accelerated; but the tone of the vessels thus stimulated to increased action, would be destroyed by too great an excitement, and the body would inevitably waste and decay. Again, were the oxygen completely extracted from the atmosphere, and nothing but nitrogen to remain, fire and flame would be extinguished, and instant destruction would be carried throughout all the departments of vegetable and animated nature. For a lighted taper will not burn for a single moment in nitrogen gas, and if an animal be plunged into it, it is instantly suffocated.

Again, not only the extraction of any one of the component parts of the atmosphere, or the alteration of their respective proportions, but even the slightest increase or diminution of their *specific gravity*, would be attended with the most disastrous effects. The nitrogen is found to be a little lighter than common air, which enables it to rise toward the higher regions of the atmosphere. In breathing, the air which is evolved from the lungs, at every expiration, consists chiefly of nitrogen, which is entirely unfit to be breathed again, and therefore rises above our heads before the next inspiration. Now, had nitrogen, instead of being a little lighter, been a slight degree heavier than common air, or of the same specific gravity, it would have accumulated on the surface of the earth, and particularly in our apartments, to such a degree as to have produced diseases, pestilence, and death, in rapid succession. But being a little lighter than the surrounding air, it flies upward, and we never breathe it again, until it enters into new and salutary combinations. Such is the benevolent skill which the Author of Nature has displayed, for promoting the comfort and preservation "of everything that lives."[*]

Further, *were the air colored*, or were its particles much larger than they are, we could never obtain a distinct view of any other object. The exhalations which rise from the earth, being rendered visible, would disfigure the rich landscape of the universe, and render life disagreeable. But the Almighty by rendering the air invisible, has enabled us not only to take a delightful and distinct survey of the objects that surround us, but has vailed from our view the gross humors incessantly perspired from animal bodies, the filth exhaled from kitchens, streets, and sewers, and every other object that would excite disgust. Again, *were the different portions of the atmosphere completely stationary*, and not susceptible of agitation, all nature would soon be thrown into confusion. The vapors which are exhaled from the sea by the heat of the sun, would be suspended, and remain forever fixed over those places from whence they arose. For want of this agitation of the air, which now scatters and disperses the clouds over every region, the sun would constantly scorch some districts, and be forever hid from others; the balance of nature would be destroyed; navigation, as it has hitherto been carried on by the agency of winds, would be useless, and we could no longer enjoy the productions of different climates. In fine, were the atmosphere capable of being frozen, or converted into a solid mass, as all other fluids are (and we know no reason why it should not be subject to congelation but the will of the Creator), the lives of every animal in the air, the waters, and the earth, would, in a few moments, be completely extinguished. But the admirable adjustment of every circumstance, in relation to this useful element, produces all the beneficial effects which we now experience, and strikingly demonstrates, that the Intelligent Contriver of all things is "wonderful in counsel, and excellent in working."

From the instances now stated, we may plainly perceive, that if the Almighty had not a particular regard to the happiness of his intelligent offspring, and to the comfort of every animated existence, or, if he wished to inflict summary punishment on a wicked world, he could easily effect, by a very slight change in the constitution of the atmosphere, the entire destruction of the human race, and the entire conflagration of the great globe they inhabit,—throughout all its elementary regions. He has only to extract one of its constituent parts,—the nitrogen from the oxygen gas,—and the grand catastrophe is at once accomplished. With what a striking propriety and emphasis, then, do the inspired writers declare, that "in Him we live, and move, and have our being;" and that "in His hand is the soul of every living thing, and the breath of all mankind."

---

[*] The necessity of atmospherical air for the support of life was strikingly exemplified in the fate of the unhappy men who died in the *Black-hole* of Calcutta. On the 20th of June, 1756, about eight o'clock in the evening, 146 men were forced, at the point of the bayonet, into a dungeon only 18 feet square. They had been but a few minutes confined in this infernal prison, before every one fell into a perspiration so profuse, that no idea can be formed of it. This brought on a raging thirst, the most difficult respiration, and an outrageous delirium. Such was the horror of their situation, that every insult that could be devised against the guard without, and all the opprobrious names that the Viceroy and his officers could be loaded with, were repeated, to provoke the guard to fire upon them, and terminate their sufferings. Before eleven o'clock the same evening, one-third of the men were dead: and before six next morning, only 23 came out alive, but most of them in a high putrid fever. All these dreadful effects were occasioned by the want of atmospheric air, and by their breathing a superabundant quantity of the nitrogen emitted from their lungs.

A great variety of other admirable properties is possessed by the atmosphere, of which I shall briefly notice only the following:—It is the vehicle of *smells*, by which we become acquainted with the qualities of the food which is set before us, and learn to avoid those places which are damp, unwholesome, and dangerous. It is the medium of *sounds*, by means of which knowledge is conveyed to our minds. Its undulations, like so many couriers, run forever backward and forward, to convey our thoughts to others, and theirs to us; and to bring news of transactions which frequently occur at a considerable distance. A few strokes on a large bell, through the ministration of the air, will convey signals of distress, or of joy, in a quarter of a minute, to the population of a city containing a hundred thousand inhabitants. So that the air may be considered as the conveyer of the thoughts of mankind, which are the cement of society. It transmits to our ears all the harmonies of music, and expresses every passion of the soul; it swells the notes of the nightingale, and distributes alike to every ear the pleasures which arise from the harmonious sounds of a concert. It produces the blue color of the sky, and is the cause of the morning and evening twilight, by its property of bending the rays of light, and reflecting them in all directions. It forms an essential requisite for carrying on all the processes of the vegetable kingdom, and serves for the production of clouds, rain, and dew, which nourish and fertilize the earth. In short, it would be impossible to enumerate all the advantages we derive from this noble appendage to our world. Were the earth divested of its atmosphere, or were only two or three of its properties changed or destroyed, it would be left altogether unfit for the habitation of sentient beings. Were it divested of its undulating quality, we should be deprived of all the advantages of speech and conversation—of all the melody of the feathered songsters, and of all the pleasures of music: and, like the deaf and dumb, we could have no power of communicating our thoughts but by visible signs. Were it deprived of its reflective powers, the sun would appear in one part of the sky in dazzling brightness, while all around would appear as dark as midnight, and the stars would be visible at noon-day. Were it deprived of its refractive powers, instead of the gradual approach of the day and the night, which we now experience—at sunrise, we should be transported all at once from midnight darkness to the splendor of noon-day: and, at sunset, should make as sudden a transition from the splendors of day to all the horrors of midnight, which would bewilder the traveler in his journey, and strike the creation with amazement. In fine, were the oxygen of the atmosphere completely extracted, destruction would seize on all the tribes of the living world throughout every region of earth, air, and sea.

Omitting, at present, the consideration of an indefinite variety of other particulars, which suggest themselves on this subject, I shall just notice one circumstance more, which has a relation both to the waters and to the atmosphere. It is a well known law of nature, that all bodies are expanded by heat, and contracted by cold. There is only one exception to this law which exists in the economy of our globe, and that is, *the expansion of water in the act of freezing.* While the parts of every other body are reduced in bulk, and their specific gravity increased by the application of cold; water, on the contrary, when congealed into ice, is increased in bulk, and becomes of a less specific gravity than the surrounding water and, therefore, swims upon its surface. Now had the case been otherwise; had water, when deprived of a portion of its heat, followed the general law of nature, and, like all other bodies, become specifically heavier than it was before, the present constitution of nature would have been materially deranged, and many of our present comforts and even our very existence, would have been endangered. At whatever time the temperature of the atmosphere became reduced to 32° of the common thermometer, or to what is called the freezing point, the water on the surface of our rivers and lakes would have been converted into a layer of ice; this layer would have sunk to the bottom as it froze; another layer of ice would have been immediately produced, which would also have sunk to the former layer, and so on in succession, until in the course of time all our rivers from the surface to the bottom, and every other portion of water capable of being frozen, would have been converted into solid masses of ice, which all the heat of summer could never have melted. We should have been deprived of most of the advantages we now derive from the liquid element, and in a short time, the face of nature would have been transformed into a frozen chaos. But in the existing constitution of things, all such dismal effects are prevented, in consequence of the Creator having subjected the waters to a law contrary to that of other fluids, by means of which the frozen water swims upon the surface, and preserves the cold from penetrating to any great depth in the subjacent fluid; and when the heat of the atmosphere is increased, it is exposed to its genial influence, and is quickly changed into its former liquid state. How admirably, then, does this *exception* to the general law of nature display the infinite intelligence of the Great Contriver of all things, and his providential care for the comfort of his creatures, when he arranged and established the economy of nature.

VARIETY OF NATURE.

As a striking evidence of Divine Intelligence, we may next consider the *immense variety which the Creator has introduced into every department of the material world.*

In every region on the surface of the globe, an endless multiplicity of objects, all differing from one another in shape, color, and motion, present themselves to the view of the beholder. Mountains covered with forests, hills clothed with verdure, spacious plains adorned with vineyards, orchards, and waving grain; naked rocks, abrupt precipices, extended vales, deep dells, meandering rivers, roaring cataracts, brooks and rills, lakes and gulfs, bays and promontories, seas and oceans, caverns and grottoes—meet the eye of the student of Nature, in every country, with a variety which is at once beautiful and majestic. Nothing can exceed the variety of the *vegetable kingdom*, which pervades all climates, and almost every portion of the dry land, and of the bed of the ocean. The immense collections of Natural History which are to be seen in the Museum at Paris show, that botanists are already acquainted with nearly fifty-six thousand different species of plants.* And yet, it is probable, that these form but a very small portion of what actually exists, and that several hundreds of thousands of species remain to be explored by the industry of future ages: for

Seminary Knolls

by far the greater part of the vegetable world still remains to be surveyed by the scientific botanist. Of the numerous tribes of vegetable nature which flourish in the interior of Africa and America, in the immense islands of New Holland, New Guinea, Borneo, Sumatra, Java, Ceylon, Madagascar, and Japan: in the vast regions of Tartary, Thibet, Siberia, and the Birman empire, in the Philippines, the Moluccas, the Ladrones, the Carolinas, the Marquesas, the Society, the Georgian, and in thousands of other islands which are scattered over the Indian and Pacific oceans—little or nothing is known by the Naturalists of Europe; and yet it is a fact which admits of no dispute that every country hitherto explored produces a variety of species of plants peculiar to itself; and those districts in Europe which have been frequently surveyed, present to every succeeding explorer a new field of investigation, and reward his industry with new discoveries of the beauties and varieties of the vegetable kingdom. It has been conjectured by some Naturalists, on the ground of a multitude of observations, that "there is not a square league of earth, but what presents some one plant peculiar to itself, or, at least, which thrives there better, or appears more beautiful, than in any other part of the world." This would make the number of species of vegetables to amount to as many millions as there are of square leagues on the surface of the earth—that is, to more than twenty-one millions.

Now every one of these species of plants differs from another, in its size, structure, form, flowers, leaves, fruits, mode of propagation, color, medicinal virtues, nutritious qualities, internal vessels, and the odors it exhales. They are of all sizes, from the microscopic mushroom, invisible to the naked eye, to the sturdy oak and the cedar of Lebanon, and from the slender willow to the Banian tree, under whose shade 7000 persons may find ample room to repose. A thousand different shades of color distinguish the different species. Every one wears its peculiar livery, and is distinguished by its own native hues; and many of their inherent beauties can be distinguished only by the help of the microscope. Some grow upright, others creep along in a serpentine form. Some flourish for ages, others wither and decay in a few months; some spring up in moist, others in dry soils; some turn toward the sun, others shrink and contract when we approach to touch them. Not only are the different species of plants and flowers distinguished from each other by their different forms, but even the different individuals of the same species. In a bed of tulips or carnations, for example, there is scarcely a flower in which some difference may not be observed in its structure, size, or assemblage of colors; nor can any two flowers be found in which the shape and shades are exactly similar. Of all the hundred thousand millions of plants, trees, herbs, and flowers, with which our globe is variegated, there are not, perhaps, two individuals precisely alike, in every point of view in which they may be contemplated; yea, there is not, perhaps, a single leaf in the forest, when minutely examined, that will not be found to differ, in certain aspects, from its fellows. Such is the wonderful and infinite diversity with which the Creator has adorned the vegetable kingdom.

His wisdom is also evidently displayed in this vast profusion of vegetable nature—in adapting each plant to the soil and situation in which it is destined to flourish—in furnishing it with those vessels by which it absorbs the air and moisture on which it feeds—and in adapting it to the nature and necessities of animated beings. As the earth teems with animated existence, and as the different tribes of animals depend chiefly on the productions of the vegetable kingdom for their subsistence, so there is an abundance and a variety of plants adapted to the peculiar constitution of every individual species. This circumstance demonstrates, that there is a precontrived relation and fitness between the internal *constitution* of the animal, and the *nature of the plants* which afford it nourishment; and shows us that the animal and the vegetable kingdoms are the workmanship of *one* and the same Almighty Being, and that, in his arrangements with regard to the one, he had in view the necessities of the other.

When we direct our attention to the tribes of *animated nature*, we behold a scene no less variegated and astonishing. Above fifty thousand species of animals have been detected and described by Naturalists, beside several thousands of species which the naked eye cannot discern, and which people the invisible regions of the waters and the air. And as the greater part of the globe has never yet been thoroughly explored, several hundreds, if not thousands, of species unknown to the scientific world, may exist in the depths of the ocean, and in the unexplored regions of the land. All these species differ from one another in color, size, and shape; in the internal structure of their bodies, in the number of their sensitive organs, limbs, feet, joints, claws, wings, and fins; in their dispositions, faculties, movements, and modes of subsistence. They are of all sizes, from the mite and the gnat up to the elephant and the whale, and from the mite downward to those invisible animalcules, a hundred thousand of which would not equal a grain of sand. Some fly through the atmosphere, some glide through the waters, others traverse the solid land. Some walk on two, some on four, some on twenty, and some on a hundred feet. Some have eyes furnished with two, some with eight, some with a hundred, and some with eight thousand distinct transparent globes, for the purposes of vision.*

Our astonishment at the variety which appears in the animal kingdom is still further increased, when we consider not only the diversities which are apparent in their external aspect, but also in their internal structure and organization. When we reflect on the thousands of movements, adjustments, adaptations, and compensations, which are requisite in order to the construction of an animal system, for enabling it to perform its intended functions;—when we consider, that every species of animals has a system of organization peculiar to itself, consisting of bones, joints, blood-vessels, and muscular motions, differing in a variety of respects from those of any other species, and exactly adapted to its various necessities and modes of existence;—and when we consider still further, the incomprehensibly delicate contrivances, and exquisite borings, polishings, claspings, and adaptations, which enter into the organization of an animated being ten thousand times less than a mite; and that the different species of these animals are likewise all differently organized from one another,—we cannot but be struck with reverence and astonishment at the *Intelligence* of that Incomprehensible Being who arranged the organs of all the tribes of animated nature, "who breathed into them the breath of life," and who continually upholds them in all their movements!

---

* The *eyes* of beetles, silk-worms, flies, and several other kinds of insects, are among the most curious and wonderful productions of the God of nature. On the head of a fly are two large protuberances, one on each side; these constitute its organs of vision. The whole surface of these protuberances is covered with a multitude of small hemispheres, placed with the utmost regularity in rows, crossing each other in a kind of lattice-work. These little hemispheres have each of them a minute transparent convex lens in the middle, each of which has a distinct branch of the optic nerve ministering to it; so that the different lenses may be considered as so many distinct eyes. Mr. Leeuwenhoek counted 6236 in the two eyes of a silk-worm, when in its *fly* state; 3180 in each eye of a beetle; and 8000 in the two eyes of the *common fly*. Mr. Hooke reckoned 14,000 in the eyes of a *drone fly;* and, in one of the eyes of a *dragon fly*, there have been reckoned 13,500 of these lenses, and consequently, in both eyes 27,000, every one of which is capable of forming a distinct image of any object, in the same manner as a common convex glass; so that there are twenty seven thousand images formed on the retina of this little animal. Mr. Leeuwenhoek having prepared the eye of a fly for that purpose, placed it a little farther from his microscope than when he would examine an object, so as to leave a proper focal distance between it and the lens of his microscope; and then looked through both, in the manner of a telescope, at the steeple of a church, which was 299 feet high, and 750 feet distant, and could plainly see, through every little lens, the whole steeple inverted, though not larger than the point of a fine needle; and then directing it to a neighboring house, saw through many of these little hemispheres, not only the front of the house, but also the doors and windows, and could discern distinctly whether the windows were open or shut—such an exquisite piece of Divine mechanism transcends all human comprehension.

Could we descend into the subterraneous apartments of the globe, and penetrate into those unknown recesses which lie toward its center, we should doubtless behold a variegated scene of wonders, even in those dark and inpenetrable regions. But all the labor and industry of man have not hitherto enabled him to penetrate farther into the bowels of the earth than the six-thousandth part of its diameter, or, about a mile and a quarter; so that we must remain forever ignorant of the immense caverns and masses of matter that may exist, and of the processes that may be going on, about its central regions. In those regions, however, near the surface, which lie within the sphere of human inspection, we perceive a variety analogous to that which is displayed in the other departments of nature. Here we find substances of various kinds formed into strata, or layers of different depths—earths, sand, gravel, marl, clay, sandstone, freestone, marble, limestone, coals, peat, and similar materials. In these stratra are found metals and minerals of various descriptions—salt, nitrate of potash, ammonia, sulphur, bitumen, platina, gold, silver, mercury, iron, lead, tin, copper, zinc, nickel, manganese, cobalt, antimony, the diamond, rubies, sapphires, jaspers, emeralds, and a countless variety of other substances, of incalculable benefit to mankind. Some of these substances are so essentially requisite for the comfort of man, that without them he would soon degenerate into the savage state, and be deprived of all those arts which extend his knowledge, and which cheer and embellish the abodes of civilized life.

If we turn our eyes upward to the regions of the atmosphere, we may also behold a spectacle of variegated magnificence. Sometimes the sky is covered with sable clouds, or obscured with mists; at other times it is tinged with a variety of hues, by the rays of the rising or the setting sun. Sometimes it presents a pure azure, at other times it is diversified with strata of dappled clouds. At one time we behold the rainbow rearing its majestic arch, adorned with all the colors of light; at another, the Aurora Borealis illuminating the sky with its fantastic coruscations. At one time we behold the fiery meteor sweeping through the air, diffusing a sparkling and brilliant light; at another, we perceive the forked lightning darting from the clouds, and hear the thunders rolling through the sky. Sometimes the vault of heaven appears like a boundless desert, particularly about the time of the rising and setting of the sun in a clear sky; and at other times adorned with an innumerable host of stars, the blazing comet, the planets in their courses, and with the moon "walking in brightness." In short, whether we direct our view to the vegetable or the animal tribes—to the atmosphere, the ocean, the mountains, the plains, or the subterranean recesses of the globe, we behold a scene of beauty, order, and *variety*, which astonishes and enraptures the contemplative mind, and constrains us to join in the devout exclamations of the Psalmist, "*How manifold are thy works*, O Lord! In wisdom hast thou made them all: the earth is full of thy riches; so is the great and wide sea, wherein are things creeping *innumerable*, both small and great beasts."

This countless variety of objects which appears throughout every department of our sublunary system, not only displays the depths of Divine Wisdom, but also presents us with a faint idea of the *infinity* of the Creator, and of the *immense multiplicity of ideas and conceptions* which must have existed in the Eternal Mind, when the fabric of our globe, and its numerous tribes of inhabitants, were arranged and brought into existence. And if every other world which floats in the immensity of space, be diversified with a similar variety of existences, altogether different from ours (as we have reason to believe, from the variety we already perceive, and from the boundless plans and conceptions of the Creator), the human mind is lost and confounded, when it attempts to form an idea of those endlessly diversified plans, conceptions, and views, which must have existed during an eternity past in the Divine Mind. When we would attempt to enter into the conception of so vast and varied operations, we feel our own littleness, and the narrow limits of our feeble powers, and can only exclaim, with the apostle Paul, "O the depth of the riches both of the wisdom and knowledge of God! how unsearchable are his counsels, and his ways (of creation and providence) past finding out!"

This characteristic of variety, which is stamped on all the works of Omnipotence, is doubtless intended to gratify the principle of curiosity, and the love of novelty, which are implanted in the human breast; and thus to excite rational beings to the study and investigation of the works of the Creator; that therein they may behold the glory of the Divine character, and be stimulated to the exercise of love, admiration, and reverence. For, as the records of Revelation, and the dispensations of Providence, display to us the various aspects of the moral character of Deity, so the diversified phenomena, and the multiplicity of objects and operations which the scenery of nature exhibits, present to us a specimen of the *ideas*, as it were, of the Eternal Mind, in so far as they can be adumbrated by material objects, and exhibited to mortals, through the medium of corporeal organs.

To convey an adequate conception of the *number* of these ideas, as exhibited on the globe on which we live, would baffle the arithmetician's skill, and set his numbers at defiance. We may, however, assist our conceptions a little by confining our attention to one department of nature; for example, the ANIMAL KINGDOM. The number of the different species of animals, taking into account those which are hitherto undiscovered, and those which are invisible to the naked eye, cannot be estimated at less than 300,000. In a human body there are reckoned about 446 muscles, in each of which, according to anatomists, there are at least ten several intentions or due qualifications to be observed—its proper figure, its just magnitude, the right disposition of its several ends, upper and lower, the position of the whole, the insertion of its proper nerves, veins, arteries, etc., so that, in the muscular system alone, there are 4460 several ends or aims to be attended to.—The bones are reckoned to be in number about 245, and the distinct scopes or intentions of each of these are above 40; in all, about 9800: so that the system of bones and muscles alone, without taking any other parts into consideration, amounts to above 14,000 different intentions or adaptations. If now we suppose, that all the species of animals above stated are differently constructed, and, taken one with another, contain, at an average, a system of bones and muscles as numerous as in the human body—the number of species must be multiplied by the number of different aims and adaptations, and the product will amount to 4,200,000,000. If we were next to attend to the many thousands of blood vessels in an animal body, and the numerous ligaments, membranes, humors, and fluids of various descriptions, the skin with its millions of pores, and every other part of an organical system, with the aims and intentions of each, we should have another sum of many hundreds of millions to be multiplied by the former product, in order to express the diversified ideas which enter into the construction of the animal world. And if we still further consider that, of the hundreds of millions of individuals belonging to each species, no two individuals exactly resemble each other—that all the myriads of vegetables with which the earth is covered are distinguished from each other by some one characteristic or another, and that every grain of sand contained in the mountains, and in the bed of the ocean, as shown by the microscope, discovers a different form and configuration from another—we are here presented with an *image* of the *infinity* of the *conceptions* of Him in whose incomprehensible mind they all existed, during countless ages, before the universe was formed.

To overlook this amazing scene of Divine intelligence, or to consider it as beneath our notice, as some have done—if it be not the characteristic of impiety, is, at least, the mark of a weak and undiscriminating mind. That man who disregards the visible displays of Infinite Wisdom, or who neglects to investigate them when opportunity offers, acts as if he considered himself already possessed of a sufficient portion of intelligence, and stood in no need of such sensible assistance to direct his conceptions of the Creator. Pride, and false conceptions of the nature and design of true religion, frequently lie at the foundation of all that indifference and neglect with which the visible works of God are treated by those who make pretensions to a high degree of spiritual attainments. The truly pious man will trace, with wonder and delight, the footsteps of his Father and his God, wherever they appear in the variegated scene of creation around him, and will be filled with sorrow and contrition of heart, that, amidst his excursions and solitary walks, he has so often disregarded "the works of the Lord, and the operation of his hands."

In fine, the variety which appears on the face of nature not only enlarges our conceptions of Infinite Wisdom, but is also the foundation of all our discriminations and judgments as rational beings, and is of the most essential utility in the affairs of human society. Such is the variety of which the features of the human countenance are susceptible, that it is probable, that no two individuals, of all the millions of the race of Adam that have existed since the beginning of time, would be found to resemble each other. We know no two human beings presently existing, however similar to each other, but may be distinguished either by their stature, their forms, or the features of their faces; and on the ground of this dissimilarity, the various wheels of the machine of society move onward, without clashing or confusion. Had it been otherwise—had the faces of men, and their organs of speech, been cast exactly in the same mold, as would have been the case had the world been framed according to the Epicurean system, by blind chance directing a concourse of atoms, it might have been as difficult to distinguish one human countenance from another, as to distinguish the eggs laid by the same hen, or the drops of water which trickle from the same orifice; and consequently, society would have been thrown into a state of universal anarchy and confusion. Friends would not have been distinguished from enemies, villains from the good and honest, fathers from sons, the culprit from the innocent person, nor the branches of the same family from one another. And what a scene of perpetual confusion and disturbance would thus have been created. Frauds, thefts, robberies, murders, assassinations, forgeries, and injustice of all kinds, might have been daily committed without the least possibility of detection. Nay, were even the *variety of tones* in the human voice, peculiar to each person, to cease, and the *handwriting* of all men to become perfectly uniform, a multitude of distressing deceptions and perplexities would be produced in the domestic, civil, and commercial transactions of mankind. But the All-wise and Beneficent Creator has prevented all such evils and inconveniences by the character of *variety* which he has impressed on the human species, and on all his works. By the peculiar features of his countenance, every man may be distinguished in the light; by the tones of his voice he may be recognized in the dark, or when he is separated from his fellows by an impenetrable partition; and his handwriting can attest his existence and individuality, when continents and oceans interpose between him and his relations, and be a witness of his sentiments and purposes to future generations.

Thus I have taken a very cursory view of some evidences of Divine Wisdom, which appear in the general constitution of the *earth*, the *waters*, and the *atmosphere*, and in the characteristic of *variety*, which is impressed on all the objects of the visible creation. When these, and other admirable arrangements in our sublunary system, are seriously contemplated, every rational and pious mind will be disposed to exclaim with the Psalmist—"There is none like unto thee, O Lord, neither are there any works like unto thy works."—"Thou art great, and dost wondrous things: thou art God alone."—"O that men would praise the Lord for his goodness, and for his wonderful works toward the children of men!"

When we consider not only the *utility*, but the *beauty* and *grandeur* of the wise arrangements of nature, what reason have we to admire and adore the goodness of the great Author of our existence? Were all the diversities of shape and color, of mountains and vales, of rivers and lakes, of light and shade, which now embellish the various landscapes of the world, to disappear, and were one unvaried scene perpetually to present itself to the eye, how dull, and wearisome, and uninteresting would the aspect of the universe appear to an intelligent mind! Although the variegated beauties which adorn the surface of our globe, and the vault of heaven, are not essential to our existence as sensitive beings, yet were they completely withdrawn, and nothing presented to the eye but a boundless expanse of barren sands, the mind would recoil upon itself, its activity would be destroyed, its powers would be confined, as it were, to a prison, and it would roam in vain amidst the surrounding waste in search of enjoyment. Even the luxuries of a palace, were it possible to procure them amidst such a scene of desolation, would become stale and insipid, and would leave the rational soul almost destitute of ideas and of mental energy, to the tiresome round of a cheerless existence. But, in the actual state of the world we live in, there is no landscape in nature, from the icebergs of Greenland to the verdant scenes of the Torrid Zone, in which objects, either of sublimity or of beauty, in boundless variety, are not presented to the view, in order to stimulate the mind to activity, to gratify its desire of novelty, and to elevate its conceptions of the Beneficent Creator.

And if the present constitution of our world displays so evident marks of beauty and benevolent design, now that it is inhabited by an assemblage of depraved intelligences, and its physical aspect deformed, in consequence of "the wickedness of man," what transporting beauties and sublimities must it have presented, when it appeared fresh from the hand of its Almighty Maker, and when all things were pronounced by him to be very *good!* After a deluge of waters has swept away many of its primeval beauties, and has broken and deranged even its subterraneous strata, this terrestrial world still presents to the eye a striking scene of beauty, order, and beneficence. But we have the strongest reason to believe, that, before sin had disfigured the aspect of this lower world, all was "beauty to the eye, and music to the ear"—that "immortality breathed in the winds, flowed in the rivers," and exhaled from every plant and flower. No storms disturbed the tranquillity of nature, nor created the least alarm in the breasts of its holy inhabitants. No earthquakes shook the ground, nor rent the foundations of nature. No volcanoes vomited their rivers of lava, nor overwhelmed the plains with deluges of fire. No barren deserts of heath and sand disfigured the rich landscape of the world—no tempests nor hurricanes tossed the ocean, nor scorching heats nor piercing colds, nor pestilence nor disease, annoyed the human frame. In the paradisaical state of the world, we may reasonably suppose, that all the elements of nature contributed directly to the pleasure and enjoyment of man, and of the other tribes of animated nature; and that they were not subjected as they now are, to the operation of those natural agents which so frequently spread destruction and ruin among the abodes of men. To suppose the contrary to have happened would be inconsistent with the state of pure and happy intelligences, and with the benignity of the Creator; and would imply, that God was either unwilling or unable to remove such physical evils. But we cannot suppose it beyond the limits of Infinite Wisdom and Omnipotence, to create and arrange a world entirely free from those evils and inconveniences which now flow from the operation of certain physical agents, without, at the same time, supposing that his power and intelligence are confined within certain bounds, beyond which they cannot pass. And, therefore, if, in the existing constitution of things, the harmony of nature is occasionally disturbed, and its beauty defaced, by earthquakes, storms, and tempests—we must remember, that the inhabitants of the earth are now a depraved race of mortals, no longer adorned with primeval purity and innocence; and that the physical economy of our globe has undergone a certain derangement, corresponding to the *moral state* of its present occupants.—But since this earth, even in its present state of degradation and derangement, presents to the view of every beholder so many objects of beauty and magnificence, and so numerous traces of Divine Beneficence—we may reasonably conclude, that scenes of Divine Wisdom and Goodness, far more glorious and transporting, must be displayed in those worlds where moral evil has never shed its malign influence, and where the inhabitants—superior to disease and death—bask forever in the regions of immortality. And therefore, however admirable the displays of Divine Wisdom may appear in the sublunary scene around us, they must be considered as inferior to those which are exhibited in many other provinces of Jehovah's empire, in so far as they are blended with those physical derangements which indicate his displeasure against the sins of men.

Were we now to direct our attention to the mechanism of animated beings; and to consider the numberless contrivances and adaptations in their organical structure and functions, a thousand instances of exquisite wisdom and design, still more striking and admirable, would crowd upon our view. For, although the general fabric of the world, and the immense variety of objects it contains, are evident proofs of a Wise and Intelligent Contriver, yet it is chiefly in the minute and delicate contrivances of organical structures, their adaptation to the purposes of life, motion, and enjoyment, and their relation and correspondence to the surrounding elements, that the consummate skill of the Great Architect of nature is most strikingly perceived. But as it forms no part of my present plan to enter on so extensive a field of illustration, on which volumes might be written, I shall content myself with merely stating an example or two. My first example shall be taken from

THE STRUCTURE OF THE HUMAN EYE.

The eye is one of the nicest pieces of mechanism which the human understanding can contemplate; but as it requires a knowledge of its anatomical structure, and of the principles of optics, to enable us to appreciate its admirable functions, I shall confine myself to a few *general* descriptions and remarks.

The eye is nearly of a globular form. It consists chiefly of three *coats* and three *humors* The first or outer coat is termed *sclerotica;* it is everywhere white and opaque, and is joined, at its anterior edge, to another which has more convexity than any other part of the globe of the eye, and, being exceedingly transparent, is called the *cornea.* These two parts are perfectly different in their structure, and are supposed, by some anatomists, to be as distinct from each other as the glass of a watch is from the case into which it is affixed.—Next within this coat is that called the *choroides,* on account of its being furnished with a great number of vessels. It serves, as it were, for a lining to the other, and is joined with that part of the eye termed the *iris.* The *iris* is an opaque membrane like the choroides, but of different colors in different eyes, as gray, black, or hazel. It is composed of two sets of muscular fibers, the one of a circular form, which contracts the hole in the middle, called the *pupil*, when the light is too strong for the eye; and the other of radial fibers, tending everywhere from the circumference of the iris toward the middle of the pupil; which fibers, by their contractions, dilate and enlarge the pupil, when the light is weak, in order to let in more of its rays.—The third coat is called the *retina*, upon which are painted the images of all visible objects, by the rays of light which flow from them. It spreads like network all over the inside of the choroides, and is nothing more than a fine expansion of the optic nerve; by which nerve the impressions of visible objects are conveyed to the brain.

The inside of the globe of the eye, within these tunics or coats, is filled with three humors called the aqueous, the crystalline, and the vitreous. The *aqueous* humor lies at the forepart of the eye, and occupies all the space between the crystalline and the prominent cornea. It has the same specific gravity and refractive power as water, and seems chiefly of use to prevent the crystalline from being easily bruised by rubbing, or by a blow — and perhaps it serves for the crystalline humor to move forward in while we view near objects; and backward, for remoter objects; without which, or some other mechanism effecting the same purpose, we could not, according to the law of optics, perceive objects distinctly when placed at different distances.—Behind the aqueous lies the *crystalline* humor, which is shaped like a double convex glass, and is a little more convex on the back than on the forepart. This humor is transparent like crystal, is nearly of the consistence of hard jelly, and converges the rays which pass through it from visible objects, to its focus at the bottom or back part of the eye.—The *vitreous* humor lies behind the crystalline, and fills up the greater part of the orb of the eye, giving it a globular shape. It is nearly of the consistence of the white of an egg, and very transparent; its forepart is concave, for the crystalline humor to lodge in, and its back part being convex, the retina is spread over it. It serves as a medium to keep the crystalline humor and the retina at a due distance. From what has been now stated, it is obvious, that the images of external objects are depicted on the retina, in an inverted position, in the same manner as the images formed by a common convex lens; but how the mind, in this case, perceives objects erect, is a question, about which the learned have been divided in their opinions.*

The ball of the eye, as now described, is situated in a bony cavity, called its orbit, composed by the junction of seven different bones, hollowed out at their edges. This cavity is, in all the vacant spaces, filled with a loose fat, which serves as a proper medium for the eye to rest in, and as a socket in which it may move. It is sheltered by the eyebrows, which are provided with hair, to prevent the descending sweat of the forehead from running down into it. As a still further protection to this delicate organ, it is furnished with the eyelid, which, like a curtain, is drawn over it with inconceivable swiftness, for its security on the approach of danger. It also serves to wipe from it superfluous moisture, and to cover it during sleep. In the upper part of its orbit it is furnished with a gland, to supply it with water sufficient to wash off dust, and to keep its outer surface moist, without which the cornea would be less transparent, and the rays of light would be disturbed in their passage; and the superfluous water is conveyed to the nose through a perforation in the bone.

For the purpose of enabling the eye to move in its socket, *six muscles* are provided. These are admirably contrived to move it in every direction, upward or downward, to the right or to the left, or in whatever direction the occasion may require; and thus we are spared the trouble of turning our heads continually toward the objects we wish to inspect. If we want to look upward, one of these muscles lifts up the orb of the eye; if we would cast our eyes to the ground, another muscle pulls them down. A third muscle moves the globe outward toward the temples, and a fourth draws it toward the nose. A fifth, which slides within a cartilaginous ring, like a cord over a pulley, and is fastened to the globe of the eye in two points, makes it roll about at pleasure A sixth lies under the eye, and is designed to temper and restrain within proper bounds the action of the rest, to keep it steadily fixed on the object it beholds, and to prevent those frightful contortions which otherwise might take place.* By these, and a multitude of other mechanical contrivances, all acting in harmonious combination, the eye, as a natural telescope and microscope, is made to advance, to recede, to move to the right, and to the left, and in every other direction; and to view near and distant objects with equal distinctness; so that a single eye, by the variety of positions it may assume, performs the office of a thousand.†

The utility of these several movements, and the pain and inconvenience which would be suffered were any of them wanting, can scarcely be conceived by any one whose eyes have always remained in a sound state. We are so much accustomed to the regular exercise of our visual organs, that we seldom reflect on the numerous delicate springs which must be set in action, before the functions of vision can with ease be performed. But were any one of the muscular organs, now described, to fail in its functions, we should soon experience so many inconveniences, as would throw a gloom on all the other comforts of life; and convince us how much we are indebted, every moment, to the provident care and goodness of our beneficent Creator, for thousands of enjoyments which we seldom think of, and for which we are never sufficiently grateful. "With much compassion, as well as astonishment, at the goodness of our loving Creator," says Dr. Nieuwentyt, "have I considered the sad state of a certain gentleman, who, as to the rest, was in pretty good health, but only wanted the use of those two little muscles that serve to lift up the eyelid, and so had almost lost the use of his sight—being forced, as long as this defect lasted, to shove up his eyelids every moment with his own hands."‡

How admirable, then, is the formation of the eye, and how grateful ought we to feel at the consideration, that we are permitted to enjoy all the transporting pleasures of vision, without the least perplexity or effort on our part! If the loss of action in a single muscle produces so many distressing sensations and efforts, what would be the consequence if all the muscles of the eye were wanting or deranged? And is it man that governs these nice and intricate movements, —or is it the eye itself, as a self-directing machine, that thus turns round, seasonably and significantly, toward every visible object? Man knows neither the whole structure of the organs of vision, nor the functions they ought to perform. The eye is only an unconscious machine in the hands of a Superior Intelligence, as a watch or a steam-engine is in the hands of a mechanic. It is God alone who constantly performs its movements, according to certain laws, which he has submitted to our inclinations and desires; "*for in him we live and move.*" We are *desirous* to see certain objects around us: this is all the share we have in the operations of our eyes; and without perplexing our understanding, without the least care or management in regard to any of the functions, we can, in a few moments, take a survey of the beauties and sublimities of an extensive landscape, and of the glories of the vault of heaven. Thus the Divine Being operates, not only in this, but in a thousand different ways, in the various senses and contrivances which belong to our animal system; and yet thoughtless and ungrateful man often inquires, in the language of doubt and hesitation, "Where is God my Maker?"—He is in us and around us, directing every movement in our animal frame to act in harmony with the surrounding elements, and to minister to our enjoyment; and it is only when his exquisite operations are deranged by external violence, or by vicious or imprudent habits, that we feel inconvenience or pain.

---

* An idea of the relative positions of the *coats* and *humors* described above, may be obtained by a simple inspection of the Frontispiece, Fig. 6.—Fig. 5 represents a *front view* of the human eye, as it appears in its natural state, and exhibits the relative positions of the *Cornea, Iris,* and *Pupil.*

* A more particular description of the muscles of the eye illustrated by two engravings, will be found in the author's volume, entitled, "The Improvement of Society by the Diffusion of Knowledge," p. 72.

† Flies and other insects, whose eyes are immovable have several thousands of distinct globes in each eye. See Note, p. 34.

‡ Nieuwentyt's Religious Philosopher, vol. i, p. 232.

Such are only a few general outlines of the structure of the eye; for no notice has been taken of the numerous minute veins, arteries, nerves, lymphatics, glands, and many other particulars which are connected with this organ. But all this delicate and complicated apparatus in the structure of the eye would have been of no use whatever for the purpose of vision, had not a distinct substance been created to act upon it, exactly adapted to its nature and functions. In order that the eye might serve as the medium of our perceptions of visible objects, *light* was formed, and made to travel from its source at the rate of 192,000 miles in a second of time. This prodigious velocity of light is doubtless essential to the nature of vision; since it actually exists, and since we find that it radiates with the same swiftness from the most distant visible star, as from the sun which enlightens our system. To abate the force of this amazing velocity, its particles have been formed almost infinitely small—a circumstance which alone prevents this delightful visitant from becoming the most tremendous and destructive element in nature. Dr. Nieuwentyt has computed that, in one second of time, there flows 418,660,000,000,000,000,000,000,000,000,000,000,000,000,000* particles of light out of a burning candle, which number contains at least 6,337,242,000,000 times the number of grains of sand in the whole earth, supposing every cubic inch of the earth to contain a million of grains. It has been justly remarked by Mr. Ferguson, and other authors, that "if the particles of light were so large, that a million of them were equal in bulk to an ordinary grain of sand, we durst no more open our eyes to the light, than suffer sand to be shot point-blank against them from the mouth of a cannon." It may also be remarked, that the property which all bodies possess of *reflecting* light, is essential to the purpose of vision, without which the splendid and variegated scene of nature would be changed into a dreadful gloom; and were the rays of light of one uniform color, and not compounded of various hues, one object could not be distinguished from another, and the beautiful aspect of our globe would instantly disappear.

Thus we see that the eye is adapted to light, and light to the eye; and in this admirable adaptation the wisdom of the Creator is strikingly displayed. For light has no effect upon the ear, or upon any other organ of sensation, so as to produce a perception of visible objects; as, on the other hand, the undulations of the air have no effect upon the eye, so as to produce the sensation of *sound*. The eye did not produce the light, nor did the light form the eye; they are perfectly distinct from each other, yet so nicely adapted in every particular, that had any one quality or circumstance been wanting in either, the functions of vision could not have been performed in the manner in which they now operate; which strikingly demonstrates, that one and the same Intelligent Being, possessed of a wisdom beyond our comprehension, formed the curious structure of the eye, and indued the rays of light with those properties of color, motion, and minuteness, which are calculated, through the medium of this organ, to produce, in sentient beings, the ideas of visible objects. And, surely, he never intended that such exquisite skill and contrivance should be altogether overlooked by rational beings, for whose pleasure and enjoyment all this benevolent care is exercised.

MANNER IN WHICH VISION IS PERFORMED.

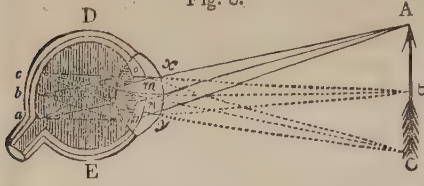
Let us now attend a little to the manner in which vision is performed, by the medium of light acting on the organs of sight. If we take a common convex glass—a reading-glass, for example—and hold it at some distance from a candle or a window-sash, placing a piece of white paper behind the glass, at the distance of its focus, the image of the candle or sash will be painted on the paper, in an inverted position. This experiment may be performed with a better effect, by darkening a room, and placing the convex glass in a hole cut out of the window-shutter, when the rays of light, flowing from the objects without, and passing through the glass, will form a picture of the objects opposite the window, on the white paper, adorned with the most beautiful colors. In a manner similar to this are the images of external objects depicted on the back part of the inner coat or membrane of the eye. The rays of light, proceeding in all directions from surrounding objects, and falling on the eye, are transmitted through the pupil; and being refracted by the different humors (particularly by the *crystalline* humor, which acts the part of a convex lens), they converge to a focus on the *retina*, where the images of visible objects are painted in an inverted position; and, by means of the optic nerve, these images are conveyed to the mind.

The following figure will perhaps more distinctly illustrate this point. Let *a b c x y* represent the globe of the eye, and A B C an object at a certain distance from it. Now, it is well know that every point of a visible object sends out rays of light in all directions; and therefore, a certain portion of the rays which flow from the object A B C, will fall upon the *cornea* between x and y, and passing through the *aqueous* humor, m n, and the *crystalline* humor, o p, and the *vitreous* humor, D E, will be converted to a focus on the retina, and paint a distinct picture, a b c, of the object A B C, in an inverted position. The rays from the point A of the object, after being refracted by the different humors, will be brought to a point at a; those from B will be converged at b; and those from C at c; and of course the intermediate rays between A B and B C will be formed between a b and b c, and the object will become visible by means of its image or representation being painted on the retina, in all the colors and proportions which belong to it. If we take a bullock's eye, and cut off the three coats from the back part, and put a piece of thin white paper over that part, and hold the eye toward the window, or any bright object, we shall see the image of the object depicted upon the paper, and in an inverted position, as stated above.

---

* That is, four hundred and eighteen septillions, six hundred and sixty sextillions.—See Appendix, Note III.

Fig. 8.



In order that we may more distinctly perceive the wonders of vision, and the numerous circumstances on which it depends, let us suppose ourselves placed on an eminence, which commands a view of a variegated and extensive landscape.—Let us suppose ourselves stationed on Arthur's Seat, or on the top of Salisbury Crags, in the vicinity of Edinburgh. Turning our face to the north-west, the city, with its castles, spires, and stately edifices, presents itself to our view. Beyond it, on the north and west, a beautiful country, adorned with villas, plantations, and fertile fields, stretches as far as the eye can reach, until the view is bounded by the castle of Stirling, at a distance of more than thirty miles. On the right hand, we behold the port of Leith, the shipping in the roads, the coast of Fife, the isles of Inchkeith and of May, and the frith of Forth gradually losing itself in the German ocean. If we suppose the length of this landscape to be forty miles, and its breadth twenty-five, it will, of course, comprehend an area of a thousand square miles.

The first circumstance which strikes the mind, is *the immense multitude of rays of reflected light* which flow in all directions, from the myriads of objects which compose the surrounding scene.—In order to form a rude idea of this infinity of radiations I fix my attention on a single object. I direct my eye to Nelson's monument, on the Calton Hill. From the parapet at the top, a thousand different points send forth a thousand different cones of rays, which, entering my eye, render the different parts of it distinctly visible, beside myriads of rays from the same points, which flow in every other direction through the open spaces of the atmosphere which surround them. How many thousands of millions, then, of different radiations must be issuing forth every moment from the whole mass of the monument! And if one object pours forth such a flood of rays, how immense must be the number of radiations which are issuing from all the objects which compose this extensive landscape! Myriads of rays, from myriads of objects, must be crossing each other in an infinity of directions, so that the mind is confounded at the apparent confusion which seems to exist in this immensity of radiations; yet every ray passes forward in the crowd, in the most perfect order, and, without being blended or confused with any other ray, produces its specific effect on every eye that is open to receive it. But this is not all: these millions of rays, which flow from the minutest points of the surrounding scene, before they can produce the sensation of vision, and form a picture of the landscape on the retina, must be compressed into a space little more than one-eighth of an inch in diameter, before they can enter the pupil of the eye; yet they all pass through this small aperture without the least confusion, and paint the images of their respective objects in exactly the same order in which these objects are arranged.—Another circumstance demands attention. The rays which proceed from the objects before me, are not all directed to the spot where I stand, but are diffused throughout every point of the surrounding space, ready to produce the same effect, wherever sentient beings are present to receive them. Were the whole inhabitants of Edinburgh placed on the sloping declivity of Arthur's Seat, and along the top of Salisbury Crags, and were millions of other spectators suspended in the surrounding atmosphere, similar sensations would be produced, and a scene similar to that which I now behold would be depicted in every eye. Amidst the infinity of cones of light, crossing each other in an infinity of directions, no confusion would ensue, but every spectator, whose eyes were in a sound state, would obtain a correct view of the scene before him; and hence it happens, that, whenever I shift my position to the right hand or to the left, other streams of light enter my eye, and produce the same effect.

Let me now attend to another circumstance, no less admirable than the preceding, and that is, the *distinct impression* which I have of the shape, color, and motion, of the multiplicity of objects I am now contemplating, and the *small space* within which their images are depicted at the bottom of my eye. Could a painter, after a long series of ingenious efforts, delineate the extensive landscape now before me on a piece of paper not exceeding the size of a silver sixpence, so that every object might be as distinctly seen, in its proper shape and color, as it now appears when I survey the scene around me, he would be incomparably superior to all the masters of his art that ever went before him. This effect, which far transcends the utmost efforts of human genius, is accomplished in a moment, in millions of instances, by the hand of Nature, or, in other words, by "the finger of God." All the objects I am now surveying, comprehending an extent of a thousand square miles, are accurately delineated in the bottom of my eye, on a space *less than half an inch* in diameter. How delicate, then, must be the strokes of that divine pencil which has formed such a picture! I turn my eyes to the castle of Edinburgh, which appears one of the most conspicuous objects in my field of view.—Supposing that portion of it which strikes my eye to be 500 feet long, and 90 in hight, I find, by calculation, that it occupies only the six-hundred-thousandth part of the whole landscape, and, consequently, fills in my eye no more than the twelve-hundred-thousandth part of an inch. I next direct my eye toward the Frith of Forth, and perceive a steamboat sailing between Queensferry and Newhaven. I distinctly trace its motion for the space of 40 minutes, at the end of which it reaches the chainpier at Newhaven, having passed over a space of five miles in length, which is but the eighth part of the *lineal* extent of the landscape in that direction; and, consequently, occupies, in the picture formed on my retina, a lineal space of only one-sixteenth of an inch in extent. And, if the boat be reckoned about 88 feet in length, its image is only the three-hundredth part of this extent; and, of course fills a space in the eye of only the four-thousand-eight-hundredth part of a *lineal* inch. Yet, my perception of the motion of the vessel could be produced by only a corresponding motion of its image in my eye; that is, by the *gradual* motion of a point one-four-thousand-eight-hundredth part of an inch in diameter, over a space one-sixteenth of an inch in length. How inconceivably fine and accurate, then, must be the impression of those strokes which the rays of light, from visible objects, produce on the retina of the eye! The mind is lost in wonder when it attempts to trace so exquisite and admirable an effect.

I take a reflecting telescope, and through it view some of the distant parts of the landscape. My wonder is still increased when I consider the new directions into which the rays of light are bent—the crossings and recrossings, the refractions and reflections, that take place between the mirrors and the lenses of the instrument, and the successive images that are formed—so that, instead of a scene of confusion, which previous to experience, might have been expected from the numerous additional bendings and intersections of the rays—I now perceive hundreds of objects, with the most perfect distinctness, which were before invisible. Rays of light from distant and minute objects, which a moment before made no sensible impression on my eye, being collected and variously modified by the telescope, now paint a vivid representation of their objects in their true figures, colors, and positions.

From a consideration of the innumerable modifications of the rays of light, and of the immense variety of effects they produce in every region of the earth—I am led to investigate *what proportion of the solar light falls upon our globe,* in order to produce so diversified a scene of sublimity and beauty. Supposing the sun's rays to be chiefly confined, in their effects, within the limits of the planetary system, since they diverge in every direction, they must fill a cubical space 3,600,000,000 miles in diameter; which consequently will contain about 24,000,000,000,000,000,000,000,000,000 of cubical miles, so that an eye, placed in any point of this vast space, would receive a distinct impression from the solar rays. The solidity of the earth is about 264,000,000,000 cubical miles, and, therefore it receives only the $\frac{1}{90000000000000000}$ part of the light which fills the sphere of the solar system. So that the light which cheers all the inhabitants of the world, and unvails such a variety of beautiful and magnificent objects, is nothing more than a *single stream* of celestial radiance out of ninety thousand billions of similar streams, which the great source of light is every moment diffusing throughout surrounding worlds. But the solar rays are not confined within the bounds of the planetary system; their influence extends, in every direction, as far as the nearest stars, filling a cubical space at least 40,000,000,000,000 miles n diameter, and which contains 33,500,000,000,000,000,000,000,000,000,000,000,000,000,000,000, or, thirty-three thousand five hundred sextillions of cubical miles. And were we to institute comparisons and calculations with respect to the possible variety of effects they might produce throughout this immense region, whole pages might be filled with figures, ciphers, and computations. We might compute how many globes similar to the earth, or any of the larger planets, might be contained within this vast space, allowing several hundreds of cubical miles of empty space around each globe — how many myriads of refractions and reflections the rays of light would suffer, in regard to the peculiar objects connected with every one of these globes — how many eyes of sentient beings might be affected by the diversities of color, shape, and motion which would thus be produced —and what a variety of shades of light and color, and what a diversity of scenery would be produced, according to the distances of the respective globes from the central luminary. After what we have just now stated, however, we may rest satisfied with joining in the pious exclamation of one who had just finished a devout survey of the structure of the human frame: "Marvelous are thy works, and that my soul knoweth right well. How precious are thy thoughts unto me, O God!" (or, as the words might be rendered), "How precious are thy wonderful contrivances concerning me, O God! how great is the sum of them? If I should count them they are more in number than the sand." In what direction soever I turn mine eyes, whatever portion of thy works I investigate, "*I am still with thee.*"* Thine infinity and unsearchable wisdom are impressed on every object, so that I feel myself every moment encompassed by thine immensity, and am irresistibly led to wonder and adore.

I shall now conclude these reflections on vision, with two or three additional remarks. It is worthy of notice, in the first place, that the eye has the power of adapting itself to objects placed at different distances. By means of some delicate pieces of mechanism, not hitherto satisfactorily explained, it can perceive, with distinctness, a large object at the distance of six miles, and the next moment it can adjust itself to the distinct perception of an object at the distance of six inches; so that it acts the part both of a telescope and a microscope, and can be *instantaneously* adjusted to perform either as the one instrument or as the other. This necessarily supposes a corresponding alteration in the state of the organ, every time we lift our eye from a *near* to look at a *distant* object. Either the *cornea* is somewhat flattened, or the crystalline humor is pushed backward, or both these changes, in combination with others, may concur in causing the rays from distant objects to unite exactly on the retina, without which, distant vision cannot be produced.—This contrivance, in whatever kind of mechanism it may consist, is one which art would vainly attempt to imitate. We can see objects that are near us with a microscope; and those that are distant with a telescope; but we should in vain attempt to see distant objects with the former, or those that are only a few inches from us with the latter, without a variety of changes being made in the apertures and positions of the glasses belonging to the respective instruments. In this respect therefore, as well as in every other, the eye is an optical instrument, incomparably superior to any instrument or imitation that art can produce; and were it not for the peculiar property now described, it would be almost unfit for the purpose of vision, notwithstanding all the other delicate contrivances which enter into its construction. If it were adjusted only for the distinct perception of distant objects, every object within the limits of an ordinary apartment would appear a mass of confusion; and were it adjusted solely for viewing objects within the limits of a few feet or inches, the glories of the heavens, and the beautiful landscape of the earth, would be vailed from our sight, as if they were enveloped in a mist.

---

* Psalm cxxxix. 14, 17, 18.

Another circumstance worthy of attention, is the power which the *pupil* of the eye possesses of contracting or enlarging the aperture or hole through which the light is admitted. When the light is too weak, the pupil is enlarged; when it is too strong, it is again contracted. Accordingly we find, that when we enter a darksome apartment, though, at first, nothing can be accurately distinguished, yet, in the course of a minute or two, when the pupil has had time to dilate, we can perceive most objects with considerable distinctness. And, on the other hand, when we pass from a dark room to an apartment lighted up with a number of lusters, we feel uneasy at the sudden glare, until the pupil has contracted itself, and excluded a portion of the superfluous rays. Were it not for this property, we should, for the most part, either be surrounded with a disagreeable gloom, or oppressed with an excessive splendor.—It is for this reason that we are unable to look upon the sun without being dazzled, and are under the necessity of closing the eyelids, or of turning away the head, when a strong light suddenly succeeds to darkness.

Again, it may not be improper to observe, how wisely the Author of Nature has fixed the distance at which we ordinarily see near objects most distinctly. This distance is generally from five to eight inches from the eye. But, had the eye been formed for distinct vision, at the distance of only *one* inch, the object would have obstructed the light, and room would have been wanting for the performance of many necessary operations, which require the hand to intervene between the eye and the object. And had the limits of distinct vision for near objects been beyond two or three feet, sufficient light would not have been afforded for the inspection of minute objects, and we could neither have written a letter nor have read a book with the same convenience and ease we are now enabled to do.

From the preceding descriptions and remarks, it will evidently appear, with what admirable skill the different parts of the organs of vision are constructed, and how nicely they are adapted to the several ends they were intended to subserve.—Were any one of these parts deficient, or obstructed in its functions, vision would either be impeded, or rendered painful and distressing, or completely destroyed. If any of the *humors* of the eye were wanting—if they were less transparent—if they were of a different refractive power—or if they were of a greater or less convexity than they now are, however minute the alteration might be, vision would inevitably be obstructed, and every object would appear confused and indistinct. If the retina, on which the images of objects are painted, were flat, instead of being concave, while objects in the middle of the view appeared distinct, every object toward the sides would appear dim and confused. If the *cornea* were as opaque as the sclerotica, to which it is joined, or if the retina were not connected with the optic nerve, no visible object could possibly be perceived. If one of the six muscles of the eye were wanting, or impeded in its functions, we could not turn it to the right; if a second were deficient, we could not turn it to the left; if a third, we could not lift it upward; if a fourth, we could not move it downward; and if it were deprived of the other two muscles, it would be apt to roll about in frightful contortions. If the eyes were placed in any other part of the body than the head—if they were much more prominent than they now are—if they were not surrounded by the bony socket in which they are lodged——and if they were not frequently covered by the eyelid—they would be exposed to a thousand accidents from which they are now protected. If they wanted moisture, and if they were not frequently wiped by the eyelids, they would become less transparent, and more liable to be inflamed; and if they were not sheltered by the eyebrows, the sweat and moisture of the forehead would frequently annoy them. Were the *light* which acts upon them devoid of color—were it not reflected from objects in every direction—were its motion less swift, or its particles much larger than they now are—in short, were any one circumstance connected with the structure of this organ, and with the modification of the rays of light, materially different from its present arrangement, we should either be subjected to the hourly recurrence of a thousand painful sensations, or be altogether deprived of the entertainments of vision.

How admirable an organ, then, is the eye, and how nicely adapted to unvail to our view the glories of the universe! Without the application of any skill or laborious efforts on our part, it turns in every direction, transports us to every surrounding object, depicts the nicest shades and colors on its delicate membranes, and

> "Takes in, at once, the landscape of the world
> *At a small inlet, which a grain might close,*
> And half creates the wondrous world we see."—YOUNG.

—How strikingly does it display, in every part of its structure and adaptations, the marks of benevolent design, and of Infinite Intelligence!—However common it is to open our eyes, and to behold, in an instant, the beauties of an extensive landscape, and however little we may be accustomed to admire this wonderful effect—there is not a doctrine in religion, nor a fact recorded in Revelation, more mysterious and incomprehensible. An excellent French writer has well observed—"The sight of a tree and of the sun, which God shows me, is as real and as immediate a Revelation as that which led Moses toward the burning bush. The only difference between both these actions of God on Moses and me is, that the first is out of the common order and economy; whereas the other is occasioned by the sequel and connection of those laws which God has established for the regulation both of man and nature."

If then, the eye of man (who is a depraved inhabitant of a world lying partly in ruins), is an organ so admirably fitted for extending our prospects of the visible creation—we may reasonably conclude, that organized beings of superior intelligence and moral purity, possess the sense of vision in a much greater degree of perfection than man in his present state of degradation—and that they may be enabled, by their *natural* organs, to penetrate into regions of the universe far beyond what man, by the aid of artificial helps, will ever be able to descry. It may not be altogether extravagant, nor even beyond the reality of existing facts, to suppose, that there are intelligences to the regions of Jupiter or Saturn, whose visual organs are in so perfect a state, that they can descry the mountains of our moon, and the continents, islands, and oceans which diversify our globe, and are able to delineate a map of its surface, to mark the period of its diurnal rotation, and even to distinguish its cities, rivers, and volcanoes. It is quite evident, that it must be equally easy to Divine Wisdom and Omnipotence, to form organs with powers of vision far surpassing what I have now supposed, as to form an organ in which the magnificent scene of heaven and earth is depicted, in a moment, within the compass of half an inch. There are animals whose range of vision is circumscribed within the limits of a few feet or inches; and, had we never perceived objects through an organ in the same state of perfection as that with which we are furnished, we could have formed as little conception of the sublimity and extent of our present range of sight, as we can now do of those powers of vision which would enable us to descry the inhabitants of distant worlds. The invention of the telescope shows, that the penetrating power of the eye may be indefinitely increased; and, since the art of man can extend the limits of natural vision, it is easy to conceive, that, in the hand of Omnipotence, a slight modification of the human eye might enable it, with the utmost distinctness, to penetrate into regions to which the imagination can set no bounds. And therefore it is not unreasonable to believe, that, in the future world, this will be one property, among others, of the *resurrection-body*, that it will be furnished with organs of vision far superior to the present, in order to qualify its intelligent inhabitant for taking an ample survey of the "riches and glory" of the empire of God.

I have dwelt somewhat particularly on the functions of the eye, in order to show, that it is only when we take a *minute* inspection of the operations of the Creator, that his Infinite Wisdom and Intelligence are most distinctly perceived. The greater part of Christians will readily admit, that the Wisdom of God is manifested in every object; but few of them take the trouble to inquire, *in what particular contrivances and adaptations* this wisdom is displayed; and, therefore, rest satisfied with vague and general views, which seldom produce any deep impression on the mind. "The works of the Lord," which are "great" and admirable, "*must be sought out* by all those who have pleasure therein;" and the more minutely they are inspected, the more exquisite and admirable do all his arrangements appear.

Were we to enter into an investigation of *the visual organs of the lower animals*, and to consider the numerous varieties which occur in their structure, position, and movements, and how nicely the peculiar organization of the eye is adapted to the general structure of the animal, and to its various necessities and modes of existence—the operation of the same inscrutable Wisdom and Intelligence would meet our eye at every step. *Birds*, for example, which procure their food by their beak, have the power of seeing distinctly at a very small distance; and, as their rapid motions through the air renders it necessary that they shoud descry objects at a considerable distance, they have two *peculiar* mechanical contrivances, connected with their organs of vision, for producing both these effects. One of these contrivances consists in a flexible rim, formed of bone, which surrounds the broadest part of the eye; and, by occasionally pressing upon its orb, shortens its focal distance, and thus enables it to inspect very near objects. The other consists of a peculiar muscle, which draws back, as occasion requires, the crystalline humor, by which means it can take a distinct view of a distant landscape, and can pass from the sight of a very near to the sight of a distant object, with rapidity and ease. In *fishes*, which live in a medium of a different refractive power from that of air, the crystalline humor has a greater degree of convexity, and more nearly approaches to a globular form than that of land animals—which conformation is essentially requisite to distinctness of vision in the watery element. A fish, of course, cannot see distinctly in air, nor a quadruped under water; and every person who has dived into the water with his eyes open, knows that though he may perceive the general forms and colors of objects, his vision is obscure and indistinct.—In *hares* and *rabbits*, the eyes are very convex and prominent, so that they can see nearly quite round them; whereas, in *dogs*, which pursue these animals, the visual organs are placed more in the front of the head, to look rather before than behind them.—Some animals, as *cats* and *owls*, which pursue their prey in the dark, have the pupil of their eye so formed as to be capable of great expansion, so that a few rays of light may make a lively impression on their retina; while the *eagle*, which is able to look directly at the sun, has its pupil capable of being contracted almost to a point.—Insects, such as the *beetle*, the *fly*, and the *butterfly*, whose eyes are incapable of motion, have several thousands of small transparent globes, set in a convex hemisphere, every one of which is capable of forming an image of an object; so that they are enabled to view the objects around them without moving their heads.—But it would be beyond the limits of my plan to prosecute this subject any further: enough has already been stated, to show that the eyes of men and of other animals are masterpieces of art, which far transcend the human understanding; and that they demonstrate the consummate wisdom of Him who planned and constructed the organical functions of the various tribes of animated existence.

I shall conclude this branch of my subject, by presenting an instance or two of *the mechanism of the bones*, and the movements it is fitted to produce.

The bones of the human frame are *articulated*, or connected together in different ways, but most frequently in the following manner:—Either, first, a bone with a round head is articulated with a cavity, and plays with it as a ball in the socket; or, second, they are connected together by a hinge-like articulation, which enables a bone to move up or down, backward or forward, like a door upon its hinges. An idea of these two motions, and the purposes they serve, may be obtained, by considering the construction of the pedestal of a telescope, and the joints on which it moves. One of the joints is of the nature of a hinge, by which a vertical motion, or a motion upward and downward, is produced. A horizontal motion, or a motion toward the right hand or the left, is produced by a pivot moving in a socket; so that, by these two motions, the telescope can be made to point in any direction. Such is the nature of the articulations in the bones, and the movements they produce; and whenever one or other of these motions, or both of them combined, is requisite for the comfort and convenience of the individual, such a power of motion is uniformly found to exist. If the movement of a joint in every direction would in any particular case be found inconvenient, the hinge-like articulation is fixed upon: but if a motion in every direction is required for the convenient use of particular members, and for the variety of evolutions which a sentient being may have occasion to make, the ball and socket articulation is combined with the former.

For example, let any person for a moment consider the joints of his fingers, and compare them with the joint at his *wrist*, where the hand is connected with the fore-arm. If he hold the back of his hand upward, he will find that he can move his fingers upward or downward; but he cannot turn them to the right hand or to the left, so as to make them describe a circular motion. He will also find that his *wrist* is capable of a similar movement, so that the hand may be bent in a vertical direction. But, in addition to this motion, it is also capable of being turned in a horizontal direction, or from one side to another. In the former case, we have an example of the hinge articulation; in the latter, it is combined with an articulation which produces nearly the same effect as a pivot moving in a socket. Now, had the joints of the fingers been capable of the same motions as the wrist, the hand would have lost its firmness, and been incapable of performing a variety of mechanical operations which require objects to be held with a steady grasp. On the other hand, if the wrist had been confined to a vertical motion, the hand would have been incapable of one out of a hundred varied movements which it can now perform with the greatest ease.* In this case, we could not have bored a hole with a gimlet, cut down corn with a sickle, digged the earth with a spade, sewed clothes with a needle, tossed up a ball, or turned up the palm of the hand, for any of the useful purposes for which that motion was ordained. In short, without the rotatory motion of the wrist, the greater part of the operations connected with gardening, agriculture, cookery, washing, spinning, weaving, painting, carving, engraving, building, and other mechanical arts, could not be performed; and such of them as could be effected, would be accomplished only with the greatest inconvenience and labor. Any person may convince himself of this, by holding his hand in a horizontal position, and preventing his wrist joint from turning round, and then by trying what operations he can easily perform without the rotatory motion; and he will soon perceive with what exquisite skill the numerous movements of our animal frames have been contrived by the Great Author of our existence. In each hand there are 27 bones, all of which are essential to the different motions we wish to perform. Every finger is composed of three bones, connected together by articulations, muscles, and ligaments. If, instead of three, each

---

* The horizontal motion of the wrist, or that motion by which the palm of the hand is alternately turned up and down, is produced chiefly by the motions of the two bones of the fore-arm, called the *radius* and the *ulna*, one of which is articulated to the *humerus*, or bone connected with the shoulder.—In the following representation (fig. 9), C is the *humerus* or shoulder bone; B is the elbow where the two bones of the fore-arm are connected with the humerus; D is the *radius*, which joins the wrist, on the side where the thumb is, and E the *ulna*, which joins the wrist on the side where the little finger is. In fig. 10, G is the radius; fig. 11, H is the ulna. The *ulna* has a hooked process marked *e*, which catches round the lower end of the humerus, forming with it a hinge joint. This bone projects beyond the head of the humerus, forming, when the arm is bent, the point of the elbow. The *radius* has a small round head B, on which it turns, without any motion of the humerus—bound to the ulna by ligaments—and as the bones of the wrist are attached to the lower end of this bone alone, and not to the ulna,—when the radius revolves the whole hand turns with it. This alternate rolling is what anatomists call *pronation* and *supination*. Flexion and extension of the arm are performed by means of the ulna, which carries the radius along with it in all its movements. While the larger part of the ulna is above, the larger part of the radius is below, so that while the former presents a large surface for articulation at the elbow, the latter does the same at the wrist, and this inverse arrangement, likewise, contributes to the uniform diameter of the fore-arm. While the fore-arm is thus attached to the humerus, the radius is attached to the wrist, so that when we turn the palm of the hand the radius rolls on the ulna by the help of a groove or hollow near each end of the bone, carrying the hand with it. So admirable, indeed, is this contrivance, that both motions may be performed at the same time; for while we are bending the arm, we may also be rotating or turning it upon its axis. To facilitate these motions, a tubercle of the radius plays into a socket of the ulna, near the elbow,—while near the wrist, the radius finds the socket, and the ulna the tubercle.

Now, had both bones been joined to the upper arm at the elbow, or both to the hand at the wrist, the motions now stated could not have been accomplished. The first bone was to be at liberty at one end, and the second at the other, by which means the two motions may be performed together. The bone which carries the fore-arm may be swinging upon its hinge at the elbow, at the very time that the other bone which carries the hand may be turning round it in its grooves. Had there been only a single bone in the fore-arm, with a ball and socket at the elbow, it might, in a certain degree, have accomplished the purpose intended; but in this case, the turning of the hand and arm would have been effected by a comparatively slow and laborious motion. Such is the wonderful care and accuracy with which our All-Wise and Benevolent Creator has contrived and adjusted every minute part and motion connected with our animal frame to subserve our convenience and pleasure. No one who is acquainted with the minute and exquisite mechanism of the human body, will dare to call in question, the skill, the design, and the forethought of the Great Artificer of that wonderful frame; and he must possess a cold and unfeeling heart, who can behold with apathy, and without reverence and gratitude, the multitudinous mass of splendid and exquisite contrivances of which he every moment feels the pleasure and advantage.

Fig. 9.

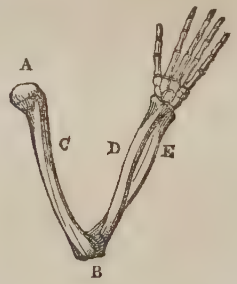


Fig. 10.

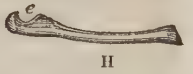
Fig. 11.



In the human hand, in particular, we perceive an instrument far superior to that of any similar part connected with the structure of the lower animals. In this hand we perceive the sensibilities to changes of temperature, to touch, and to motion, combined with a facility in the joints of unfolding and moving in every possible degree and direction, and in a manner inimitable by any artifice of joints and levers. In all the movements of human beings, it is the *hand* that guides them in their industry and mental acquisitions. By its assistance they have drained unwholesome marshes—transformed deserts into fruitful fields—turned the course of rivers—banked out the headlong sea—cleared the thickest forests, and caused cities, temples, and palaces to arise where the wild beasts of the forests formerly roamed at large. In short, by this instrument Man has been enabled to prosecute his course along pathless oceans and through the region of the clouds—to measure time and space—to investigate the wonders of the earth and of the heavens, and to promote his progress toward intellectual perfection,—and, without it, scarcely any science or department of human knowledge could be acquired or cultivated—supposing the whole human race to have been destitute of this instrument.

finger were composed of only one bone, it would be quite impossible for us to grasp a single object.

The same admirable contrivance may be perceived in the movements of which the *head* is susceptible. It was requisite, in order to our convenience and comfort, that we should be enabled to move our head backward or forward—to look up toward the heavens, or downward to the ground. It was also expedient that it should have a power of turning to the right or to the left, so as to take in a considerable portion of a circle, without being under the necessity of turning round the whole body. Accordingly we find that both these motions are provided for, in the manner in which the head is connected with the *vertebræ*. The head rests upon the uppermost of these bones, to which it is connected by a hinge joint, similar to those in the fingers, which allows it to move backward and forward; and by means of a round, longish process, or projection, which moves in a socket, it is enabled to move horizontally, as upon an axis. Had the first motion been wanting, we could not have looked up to the zenith, without lying flat on our back; nor could we have looked to the ground, without placing our bodies in a prone position; and, in such a case, we could never have seen our own feet, unless when they were bent considerably forward. Had the second motion been wanting, we could have looked to nothing, except the objects directly before us, without the trouble of turning round the whole body, either to the right or to the left. But, in the construction of our corporeal system, everything is so arranged and adapted to another, as at once to contribute to ease and facility of motion, in all the varied operations and movements we have occasion to perform; which circumstance forcibly demonstrates both the benevolent intentions and the admirable wisdom of Him "whose hands have made and fashioned us," and who "breathed into our nostrils the breath of life."

The above are only two or three out of a hundred of similar instances, which might be produced to show the benevolent care which has been exercised in arranging and articulating the system of bones of which the propwork of the human frame is composed. Were we to enter into an investigation of the actions and uses of the various muscles, the wonderful system of veins and arteries, the action of the heart, stomach, and bowels; the process of respiration, and insensible perspiration, and the system of nerves, glands, lymphatics, and lacteals—a thousand instances of Divine wisdom and beneficence would crowd upon our view, which could not fail to excite the pious and contemplative mind to join in the devotions of the "sweet singer of Israel:"—"I will praise thee; for I am fearfully and wonderfully made: marvelous are thy works, and that my soul knoweth right well'"—But as I intended to present only a few *specimens* of the Wisdom of God, as displayed in the construction of the material world, I shall conclude this department of my subject with a single reflection.[*]

How foolish and ungrateful is it for rational beings to overlook the wise and benevolent arrangements of the Creator, in the material universe. How many thousands of human beings pass their existence without once reflecting on the numerous evidences of Divine Wisdom and Beneficence which appear around them, or feeling the least spark of gratitude for their preservation and comforts, to that Being "in whose hand their breath is, and whose are all their ways!" Yea, how many are there who consider themselves as standing high in the ranks of the Christian profession, who affect to look down with a certain degree of contempt on the study of the material works of God, as if it were too gross a subject for their spiritual attainments! They profess to trace the wisdom of God in the Scriptures, and to feel gratitude for his pardoning mercy; but they seldom feel that gratitude which they ought to do for those admirable arrangements in their own bodies, and in the elements around them, by which their lives are preserved, and their happiness promoted; and even seem to insinuate that they have little or nothing to do with the contrivances of the God of Nature. They leave it to the genius of infidel philosophers to trace the articulation of the bones, the branchings of the veins and arteries, the properties of light, and the composition of the atmosphere, while they profess to feast their minds on more sublime and spiritual entertainments. But surely such astonishing displays of the wisdom and benignity of the Most High, as creation exhibits, were never intended to be treated by his intelligent offspring with apathy or indifference; and to do so must indicate a certain degree of base ingratitude toward Him whose incessant energy sustains the whole assemblage of sentient and intelligent beings, and who displays himself, in their construction and preservation, to be "wonderful in counsel and excellent in working." Shall we imagine, that because God stands in the gracious relation of our Redeemer, he has ceased to stand in the relation of our Creator and Preserver? Or shall we consider those subjects as unworthy of our attention, which are the theme of the praises of the heavenly host?[*] Can we suppose that the Almighty displayed his infinite wisdom in the curious organization of the human eye, that man—the only being in this world who is endowed with faculties capable of appreciating its structure, and for whose use and entertainment it was intended—should overlook such a wonderful piece of Divine workmanship, and feel no gratitude for the bestowment of so admirable a gift? Shall we extol the ingenuity displayed in a clock or a watch, in a chess-player, or a steam-engine, and shall we feel no sentiment of admiration at the view of millions of instances of Divine mechanism, which infinitely transcend the powers of the human understanding? To act in this manner, as too many are disposed to do, is unworthy of man, both as a Christian and as an intelligent agent. Such was not the conduct of the inspired writers; their spirituality of views did not lead them to neglect the contemplation of *any* of the works of God. "I will meditate on *all* thy works," says the Psalmist, "and talk of all thy doings; I will utter abundantly the memory of thy great goodness, and speak of all thy wondrous works." Accordingly we find, that the wonders of the human frame, the economy of the animal and the vegetable tribes, the scenery of the "dry land," and of the "mighty deep," and the glories of the heavens, were the frequent subjects of their devout contemplation. They considered them in relation to the unceasing agency of God, by whom they were formed and arranged, and as declaring his Wisdom, Goodness, and Omnipotence; and with this view ought all the scenes of the visible creation to be investigated by his intelligent creatures.

---

[*] Those who wish to prosecute this subject, particularly that part of it which relates to the contrivances of Divine Wisdom which appear in the animal system, will find ample gratification in Nieuwentyt's "Religious Philosopher," Vol. I, Bell's Bridgewater Treatise on "The Hand," and Dr. Paley's "Natural Theology." A variety of useful remarks on this subject will also be found in "Ray's Wisdom of God in the Creation," Derham's "Physico-Theology," and Bonnet's "Contemplation of Nature."

[*] Revelation iv. 11.

We have reason to believe that it is owing, in part, to want of attention to the Divine wisdom and beneficence, as exhibited in the construction of the visible world, that many professed Christians entertain so vague and confused ideas respecting the wisdom and goodness of Deity, as displayed in the economy of Redemption. The terms, Wisdom, Goodness, and Beneficence, in their mouths, become words almost without meaning, to which no precise or definite ideas are attached; because they have never considered the instances and the evidences of these attributes, as displayed in the material creation. And if our minds have not been impressed with a sense of the wisdom and beneficence of God, in those objects which are presented to the external senses, we cannot be supposed to have luminous and distinct ideas of those spiritual objects and arrangements which are removed beyond the sphere of our corporeal organs. For all our ideas in relation to Religion and its objects, are primarily derived from the intimations we receive of external objects, through the medium of our senses; and, consequently, the more clearly we perceive the agency of God in his visible operations, the more shall we be qualified to perceive the wisdom and harmony of his dispensations, as recorded in the volume of inspiration.

We live in a world, all the arrangements of which are the effects of infinite wisdom. We are surrounded with wonders on every hand; and therefore we cease to admire, or to fix our attention on any one of the wonders daily performed by God. We have never been accustomed to contemplate, or to inhabit a world where benevolence and wisdom are not displayed; and therefore we are apt to imagine that the circumstances of our terrestrial existence could not have been much otherwise than they actually are. We behold the sun in the morning ascending from the east—a thousand shining globes are seen in the canopy of the sky when he has disappeared in the west. We open our eyelids, and the myriads of objects which compose an extensive landscape are in a moment painted on our retina,—we wish to move our bodies, and in an instant the joints and muscles of our hands and feet perform their several functions. We spread out our wet clothes to dry, and in a few hours the moisture is evaporated. We behold the fields drenched with rain, and in a few days it disappears and is dispersed through the surrounding atmosphere, to be again embodied into clouds. These are all *common* operations, and therefore thoughtless and ungrateful man seldom considers the obligations he is under to the Author of his existence, for the numerous enjoyments which flow from these wise arrangements. But were the globe we inhabit, and all its appendages, to remain in their present state—and were only the principle of *evaporation* and the *refractive* and *reflective properties of the air* to be destroyed—we should soon feel, by the universal gloom which would ensue, and by a thousand other inconveniences we should suffer, what a miserable world was allotted for our abode. We should most sensibly perceive the wisdom and goodness we had formerly overlooked, and would most ardently implore the restoration of those arrangements for which we were never sufficiently grateful. And why should we not *now*—while we enjoy so many comforts flowing from the plans of Infinite Wisdom—have our attention directed to the benevolent contrivances within us and around us, in order that grateful emotions may be hourly arising in our hearts to the Father of our spirits? For the essence of true religion consists chiefly in *gratitude* to the God of our life, and the Author of our salvation; and every pleasing sensation we feel from the harmonies and the beauties of nature, ought to inspire us with this sacred emotion.—"Hearken unto this, O man! stand still and consider the wonderful works of God. Contemplate the balancings of the clouds, the wondrous works of Him who is perfect in knowledge." "He hath made the earth by his power, he hath established the world by his wisdom. When he uttereth his voice, there is a noise of waters in the heavens; he causeth the vapors to ascend from the ends of the earth, and bringeth the winds out of his treasuries." While it is shameful for man to be inattentive to the wonders which surround him, what can be more pleasing and congenial to a rational and devout mind than contemplations on the works of the Most High? "What can be more gratifying," says Sturm, "than to contemplate in the heavens, in the earth, in the water, in the night and day, and, indeed, throughout all nature, the proofs which they afford of the wisdom and purity, and the goodness of our great Creator and Preserver! What can be more delightful than to recognize, in the whole creation, in all the natural world, in everything we see, traces of the ever-working providence and tender mercy of the great Father of all."

SECTION IV.

On the goodness or benevolence of the Deity

The benevolence of God is that perfection of his nature, by which he communicates happiness to the various ranks of sensitive and intelligent existence.

The system of Nature, in all its parts, exhibits an unbounded display of this attribute of the Divine Mind, both in relation to man, and in relation to the subordinate tribes of animated existence. In relation to *Man*—the magnificence and glory of the heavens—the variegated coloring which is spread over the scene of nature—the beautiful flowers, shrubs, and trees, with which the earth is adorned, which not only delight the eye, but perfume the air with their delicious odors—the various kinds of agreeable sounds that charm the ear—the music of the feathered songsters, which fill the groves with their melody—the thousands of pleasant images which delight the eye, in the natural embellishments of creation—the agreeable feelings produced by the contact of almost everything we have occasion to touch—the pleasure attached to eating, drinking, muscular motion, and activity—the luxuriant profusion and rich variety of aliments which the earth affords—and the interchanges of thought and affection—all proclaim the Benevolence of our Almighty Maker, and show, that the communication of happiness is one grand object of all his arrangements. For these circumstances are not *essentially* requisite to our existence. We might have lived and breathed, and walked, though everything we touched had produced pain; though everything we ate and drank had been bitter; though every movement of our hands and feet had been accompanied with uneasiness and fatigue; though every sound had been as harsh as the saw of the carpenter; though no birds had warbled in the groves; though no flowers had decked the fields, or filled the air with their perfumes; though one unvaried scene of dull uniformity had prevailed, and beauty and sublimity had been swept from the face of nature; though the earth had been covered with a mantle of black, and no radiant orbs had appeared in our nocturnal sky. But what a miserable world should we then have inhabited, compared with that which we now possess! Life would have passed away without enjoyment, and pain would have overbalanced the pleasures of existence. Whereas, in the existing constitution of things, all the objects around us, and every sense of which we are possessed, when preserved in its natural vigor, have a direct tendency to produce pleasing sensations, and to contribute to our enjoyment: and it is chiefly when we indulge in foolish and depraved passions, and commit immoral actions, that the benevolent intentions of the Deity are frustrated, and pain and misery produced.

Had the Creator of the world been a malevolent being, and possessed of infinite power and intelligence, every arrangement of nature would have been almost the reverse of what we now find it. The production of *evil*, and of pain in sensitive beings, would have been the *aim* of the contriver in all his operations and allotments. All design in the frame of the universe, and all that wisdom and intelligence which we now admire in the adaptations of the parts and functions of animals to their necessities and to the constitution of nature around them—we should have dreaded as contrivances to produce painful sensations, and to render them acute and permanent. Instead of ease, and enjoyment, and delight, in the exercise of our functions and faculties—the ordinary state of the lower animals and of human beings would have been a state of trouble, disease, dejection, and anguish. Every breath of air might have cut us like the point of a dagger, or produced a pain like that of swallowing aquafortis or sulphuric acid.* Every touch might have been felt like the sting of a nettle, or like the rubbing of salt upon a festering wound. Every taste would have been bitter as gall and wormwood, and every sound harsh and dissonant, or as a hideous scream. All our senses, instead of being the sources of pleasure, as they now are, would have been the instruments of pain and torture. The lower animals, instead of ministering to our delight and necessities, would have been formed so as to torment, to harass, and annoy us. The cow and the goat would have afforded us no milk, nor the bee its honey, nor would the birds of the air have charmed us with their music. Dismal and haggard objects would have been strewed over the whole face of creation, and all would have appeared a melancholy gloom, without beauty or variety. The fields would have wanted their delightful verdure, their diversified aspect, and the beautiful flowers with which they are now adorned. The fire might have scorched without warming us, and water, instead of refreshing us, might have produced intolerable pain. The light might have been without color; it might have dazzled instead of cheering us, and prevented distant objects from being perceived. Our eye-balls might have wanted the muscles which now enable them to move with ease in every direction, and every ray of light might have affected them with pain. The ground might have been formed so soft and yielding, that at every step we should have sunk like persons walking in a quagmire.—In short, our imaginations, in such a case, would have presented to us little else than frightful specters and objects of terror and alarm,—and our minds have been filled with dismal forebodings and dreadful expectations. But, every arrangement in the system of nature, as it is now constituted, is directly the reverse of what we have now supposed. And this consideration demonstrates, that the Great Creator of the universe is the God of Love, whose mercy and benevolence are displayed toward every rank of sensitive and intelligent existence, and these attributes, we are assured, will never cease in their operations, so long as the universe endures.

If we consider, further, that the inexhaustible bounty of the Creator, and the numerous pleasures we enjoy, are bestowed upon a guilty race of men, the Benevolence of the Deity will appear in a still more striking point of view. Man has dared to rebel against his maker; he is a depraved and ungrateful creature. The great majority of our race have banished God from their thoughts, trampled upon his laws, neglected to contemplate his works, refused to pay him that tribute of reverence and adoration which his perfections demand, have been ungrateful for his favors, have blasphemed his Name, and have transferred to "four-footed beasts and creeping things," that homage which is due to him alone. It has been the chief part of their employment, in all ages, to counteract the effects of his Beneficence, by inflicting injustice, oppression, and torture upon each other; by maiming the human frame, burning cities and villages, turning fruitful fields into a wilderness, and, by every other act of violence, carrying death and destruction through the world. And if *water*, *air*, and the *light of heaven*, had been placed within the limits of their control, it is more than probable, that whole nations would have been occasionally deprived of these elements, so essential to human existence. Yet, notwithstanding the prevalence of such depraved dispositions, the streams of Divine benevolence toward our apostate race have never yet been interrupted. The earth has never stopped in its career, and thrown nature into a scene of confusion; the light of heaven has never ceased to illume the world; the springs of water have never been dried up, nor has the fertile soil ceased to enrich the plains with golden harvests. God "hath not left himself without a witness" to his beneficence, in any age, in that he hath unceasingly bestowed on the inhabitants of the world, "rain from heaven, and fruitful seasons, filling their hearts with food and gladness." This is one of the characters of Deity which forms the most perfect contrast to the selfish and revengeful dispositions of man, which as far transcends human benevolence as the heavens in extent surpass the earth—a character calculated to excite our highest love and admiration, and which we are called upon, in the Sacred Oracles, to imitate and revere: "Be ye merciful, as your Father who is in heaven is merciful; for he maketh his sun to rise on the evil and on the good, and sendeth rain on the just and on the unjust." "O that men would praise the Lord for his goodness, and for his wonderful works to the children of men!"

From such considerations we learn, even from the system of nature, that *mercy* is an attribute of the Deity; for if mercy consists in bestowing favors on those who are unworthy, or who meri punishment, the greatest sinners in all ages have shared in it, and every individual of the human race, now existing, enjoys a certain portion of those comforts which flow from the benevolent arrangements which the Creator has established: "He maketh the sun to rise *on the evil* and on the good." Though the nations in ancient times, as well as at present, "walked in their own ways," indulging in impiety, falsehood, lewdness, war, devastations, revenge, abominable idolatries, and every other violation of his law, he still supported the functions of their animal frames, and caused the influences of the sun, the rains, and the dews, to descend upon their fields, that they might be refreshed with his bounty, and filled "with food and gladness." If mercy were not an essential attribute of the Deity, he would have cut them down in the midst of their first transgressions, shattered to pieces the globe on which they dwelt, and buried them in eternal oblivion. But whether Divine mercy will extend to the final forgiveness of sin, and the communication of eternal happiness to such beings, can be learned only from the discoveries of revelation.

---

* Sulphuric acid consists of 75 parts *oxygen*, and 25 parts *nitrogen*, which form the constituent parts of the air we breathe, only in a different proportion. Were this proportion materially altered, we should feel the most excruciating pain in attempting to breathe it in some of its combinations.

In relation to the *inferior animals*—the immense multitude of living creatures with which the earth is replenished is a striking evidence of the vast profusion of Divine Beneficence. More than a hundred thousand species of animated beings are dispersed through the different regions of the air, the water, and the earth, beside myriads which are invisible to the unassisted eye. To estimate the number of individuals belonging to any one species is beyond the power of man. What countless myriads of herrings, for example, are contained in a single shoal, which is frequently more than six miles long, and three miles broad! To estimate the number of individuals in all the different species, would therefore be as impossible as to count the grains of sand in the Arabian deserts. There is not a single spot in any region of the globe but what teems with animated beings. Yet all this vast assemblage of sensitive existence is amply provided for by the bountiful Creator. "These all wait upon him, and he giveth them their meat in due season." They enjoy not only life, but also a *happy* existence. The sportive motions and gesticulations of all the animal tribes—the birds skimming through the air, warbling in the groves, and perching on the trees—the beasts of the field bounding in the forests and through the lawns—the fishes sporting in the waters—the reptiles wriggling in the dust—and the winged insects, by a thousand wanton mazes—all declare that they are rejoicing in their existence, and in the exercise of those powers with which the Creator has furnished them. So that wherever we turn our eyes, we evidently perceive that "the earth is full of the goodness of the Lord," and that "his tender mercies are over all his works."

This subject is boundless; but it would be inconsistent with the limited plan of this work to enter into any particular details. And it is the less necessary, when we consider that every instance of Divine Wisdom, is at the same time, an instance of *benevolence;* for it is the ultimate object of all the wise contrivances in the system of Nature, that happiness may be communicated to the various ranks of sensitive and intelligent existence. *Goodness* chooses the *end*, and *wisdom* selects the most proper *means* for its accomplishment; so that these two attributes must always be considered in simultaneous operation. And therefore, the instances I have already specified of the wisdom and intelligence of the Creator may also be considered as exemplifications of Divine Benevolence. I shall therefore conclude this topic with the following extract from Dr. Paley:—

"Contrivance proves design; and the prominent tendency of the contrivance indicates the disposition of the designer. The world abounds with contrivances; and all the contrivances we are acquainted with are directed to beneficial purposes. Evil, no doubt, exists; but it is never, that we can perceive, the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inseparable from it; or even, if you will, let it be called a defect in the contrivance, but it is not the *object* of it. This is a distinction that well deserves to be attended to. In describing implements of husbandry, you would hardly say of a sickle, that it was made to cut the reaper's fingers, though from the construction of the instrument, and the manner of using it, this mischief often happens But if you had occasion to describe instruments of torture or execution,—this, you would say, is to extend the sinews; this to dislocate the joints; this to break the bones; this to scorch the soles of the feet. Here pain and misery are the very *objects* of the contrivance. Now, nothing of this sort is to be found in the works of Nature. We never discover a train of contrivance to bring about an evil purpose. No anatomist ever discovered a system of organization calculated to produce pain and disease; or, in explaining the parts of the human body, ever said, this is to irritate; this to inflame; this duct is to convey the gravel to the kidneys; this gland to secrete the humor which forms the gout. If, by chance he come at a part of which he knows not the use, the most he can say is, that it is useless; no one ever suspects that it is put there to incommode, to annoy, or torment. Since, then, God hath called forth his consummate wisdom to contrive and provide for our happiness, and the world appears to have been constituted with this design at first, so long as this constitution is upheld by him, we must, in reason, suppose the same design to continue."*

Thus I have endeavored, in this and the preceding section, to exhibit a few specimens of the Wisdom and Goodness of God in the system of nature. These might have been multiplied to an indefinite extent; but the instances adduced, I presume, are sufficient to show, that the economy of the material world is not altogether a barren subject to a pious and contemplative mind. Every intelligent believer in Revelation will readily admit, that it would be a highly desirable object, to induce upon the mass of Christians such a habit of devout attention to the visible works of creation, as would lead them, in their social and solitary walks, to recognize the agency of God in every object they behold; to raise their thoughts to him as the Great First Cause, and to expand their hearts with emotions of gratitude. How very different must be the sentiments and the piety of the man who looks on the scene of wisdom and magnificence around him with a "brute unconscious gaze," as thousands of professed Christians do—and the grateful and pious emotions of him who recognizes the benevolent agency of God in the motions of his fingers and eyeballs; in the pulsation of his heart; in the picture of external objects every moment formed on his retina; in the reflection of the rays of light, and the diversified colors they produce; in the drying of his clothes; in the constitution of the atmosphere; in the beauty and magnificence of the earth and the heavens; and in every other object that meets his eye in the expanse of nature! The numberless astonishing instances of Divine agency, which everywhere present themselves to our view in the scene around us, seem evidently intended to arrest the mind to a consideration of an "ever-present Deity;" and I envy not the sentiments or the feelings of that man, who imagines that he stands in no need of such sensible mediums, to impress his mind with a sense of the benevolent care and *omnipresence* of God

---

* Paley's Moral Philosophy, Book II, Chap. v.

CHAPTER II.

CONTAINING A CURSORY VIEW OF SOME OF THE SCIENCES WHICH ARE RELATED TO RELIGION AND CHRISTIAN THEOLOGY.

Theology has generally been viewed as a study of a very limited range: and hence, when it has been admitted into the circle of the sciences, a much smaller space has been allotted for its discussion than has been devoted to almost any other department of human knowledge. When considered, however, in its most extensive sense—in its relations to the Divine Being—to his past and present dispensations toward the human race—to the present circumstances and the future destiny of man—and to the physical and moral condition of all the sentient and intelligent beings of which we have any intimation—it ought to be viewed as the most varied and comprehensive of all the sciences; as embracing, within its extensive grasp, all the other departments of useful knowledge both human and divine. As it has God for its object, it must include a knowledge of the universe he has formed—of the movements which are continually going on throughout the wide extent of his empire, in so far as they lie open to our inspection—of the attributes which appear to be displayed in all his operations—of the moral laws he has framed for the regulation of holy intelligences—of the merciful arrangements he has made for the restoration of fallen man—of the plans by which the knowledge of his will is to be circulated and extended in the world in which we live—of the means by which truth, and moral purity, and order, are to be promoted among our apostate race, in order to their restoration to the happiness they have lost—together with all those diversified ramifications of knowledge, which have either a more remote or a more immediate bearing on the grand objects now specified. Like the lines which proceed from the circumference to the center of an immense circle—all the *moral** arts and sciences which have been invented by men—every department of human knowledge, however far it may, at first sight, appear to be removed from religion—may be considered as having a direct bearing on Theology, as the grand central point, and as having a certain tendency to promote its important objects.

It is much to be regretted, that Theology has so seldom been contemplated in this point of view—and that the sciences have been considered rather as so many independent branches of secular knowledge, than as subservient to the elucidation of the facts and doctrines of religion, and to the accomplishment of its benevolent designs. Hence it has happened that Philosophy and Religion, instead of marching hand in hand to the portals of immortality, have frequently set themselves in hostile array; and combats have ensued equally injurious to the interests of both parties. The Philosopher has occasionally been disposed to investigate the economy of Nature, without a reference to the attributes of that Almighty Being who presides over its movements, as if the universe were a self-moving and independent machine; and has, not unfrequently, taken occasion, from certain obscure and, insulated facts, to throw out insinuations hostile to the truth and the character of the Christian Revelation. The Theologian, on the other hand, in the heat of his intemperate zeal against the infidel philosopher, has unguardedly, been led to declaim against the study of science, as if it were unfriendly to religion—has, in effect, set the works of God in opposition to his word—has confounded the foolish theories of speculative minds with the rational study of the works of Deity—and has thus prevented the mass of mankind from expanding their minds, by the contemplation of the beauties and sublimities of nature.

It is now high time that a complete reconciliation were effected between these contending parties. Religion ought never to disdain to derive her supports and illustrations from the researches of science; for the investigations of philosophy into the economy of Nature, from whatever motives they may be undertaken, are nothing else than an inquiry into the plans and operations of the Eternal Mind. And Philosophy ought always to consider it as her highest honor to walk as a handmaid in the train of that religion which points out the path to the regions of eternal bliss. By their mutual aid, and the subserviency of the one to the other, the moral and intellectual improvement of man will be promoted, and the benevolent purposes of God in the kingdom of providence, gradually accomplished. But, when set in opposition to each other, the human mind is bewildered and retarded in its progress, and the Deity is apt to be considered as set in opposition to himself—as proclaiming one system of doctrines from the economy of revelation, and another, and an opposite system, from the economy of nature. But if the Christian Revelation, and the system of the material world, derived their origin from the same Almighty Being, the most complete harmony must subsist between the revelations they respectfully unfold; and the apparent inconsistencies which occur, must be owing chiefly to the circumstances of our present station in the universe, and to the obscure and limited views we are obliged to take of some of the grand and diversified objects they embrace. And therefore we have reason to believe, that when the system of nature shall be more extensively explored, and the leading objects of revelation contemplated in a clearer light, without being tinged with the false coloring of party opinions and contracted views, and when rational inquirers shall conduct their researches with a greater degree of reverence, humility, and Christian temper—the beauty and harmony of all the plans and revelations of the Deity, in reference both to the physical and the moral world, will be more distinctly perceived and appreciated.

---

* The epithet *moral* is here used in its application to arts, because there are certain arts which must be considered as having an *immoral* tendency, such as the art of war, the art of boxing, of gambling, etc., and which, therefore, cannot have a direct tendency to promote the objects of religion.

In the following cursory sketches, it forms no part of my plan to trace even an *outline* of the different sciences which are connected with religion, much less to enter into any particular details in relation to their facts and principles. It would be comparatively easy to fill up the remaining sheets of this volume with skeletons of the different sciences; but such meager details as behoved to be brought forward, could not be interesting to the general reader, and would fail in accomplishing the objects proposed. My design simply is, to select some leading facts, or general truths, in relation to some of the physical sciences, for the purpose of showing their connection with the objects of religion, and the interests of rational piety. At the same time, such definite descriptions will be given as will enable common readers to appreciate the objects and bearings of the different branches of knowledge which may be presented to their view.

The first science* I shall notice, is that of

NATURAL HISTORY.

This science, taken in its most comprehensive sense, includes a knowledge and description of all the known facts in the material universe.

It is to be regretted, that most books published under the title of *Natural History*, to which common readers have access, contain nothing more than a general description of animals, as if this science were confined merely to one class of beings; whereas there is an infinite variety of other objects seldom noticed, which would appear no less interesting, and, in some instances, much more novel and gratifying to the general reader, and to the youthful mind. All the diversified forms of matter, whether existing on the surface or in the bowels of the earth, in the ocean, the atmosphere, or in the heavens, form the legitimate objects of this department of the science of nature.

Were we, therefore, to sketch a comprehensive outline of the subjects of Natural History, we might, in the first place, take a cursory survey of the globe we inhabit, in reference to its magnitude, figure, motions, and general arrangements—the form, relations, and extent of its continents—the numerous islands which diversify the surface of the ocean—the magnitude, the direction, and the extent of its rivers, and the quantity of water they pour into the ocean—the direction, elevation, and extent of the different ranges of mountains which rise from its surface—the plains, morasses, lakes, forests, dells, and sandy deserts, which diversify its aspect—the extent, the motions, the color, and the different aspects of the ocean, and the facts which have been ascertained respecting its saltness, its depth, its bottom, and its different currents. We might next take a more particular view of some of the most remarkable objects on its surface, and give a detail of the facts which are known respecting the history of *volcanoes*—their number—the countries in which they are situated—the awful phenomena they exhibit—and the devastations they have produced—the history of *earthquakes*, their phenomena and effects, and the countries most subject to their ravages—basaltic and rocky wonders, natural bridges, precipices, cataracts, ice islands, icebergs, glaciers, whirlpools, mineral wells, reciprocating fountains, boiling springs, sulphuric mountains, bituminous lakes, volcanic islands—the various aspects of nature in the different zones, and the contrasts presented between the verdant scenes of tropical climes, and the icy cliffs of the polar regions. We would next take a survey of the subterraneous wonders which lie beneath the surface of the earth—the immense chasms and caverns which wind in various directions among the interior strata of our globe—such as the great Kentucky cavern, and the grotto of Antiparos—the mines of salt, coal, copper, lead, diamond, iron, quicksilver, tin, gold, and silver—the substances which compose the various strata, the fossil bones, shells, and petrifactions which are imbedded in the different layers, and the bendings and disruptions which appear to have taken place in the substances which compose the exterior crust of the earth. We might next survey the *atmosphere* with which the earth is environed, and give a detail of the facts which have been ascertained respecting its specific gravity and pressure, the elementary principles with which it is compounded, its refractive and reflective powers, and the phenomena which result from its various properties and modifications—the *meteors* which appear in its different regions—thunder and lightning, winds, hail, rain, clouds, rainbows, parhelias or mock-suns, meteoric stones, the aurora borealis, luminous arches, ignes fatui, the mirage, the fata morgana, hurricanes, monsoons, whirlwinds and waterspouts, sounds and echoes.

In prosecuting our survey of sublunary nature, we would next advert to the various orders of the *vegetable tribes*—their anatomical structure—the circulation of their juices—the food by which they are nourished—the influence of light and air on their growth and motions—their male and female organs—their periods of longevity—their modes of propagation—their diseases and dissolution—their orders, genera, and species—their immense variety—their influence on the salubrity of the atmosphere—the relation which their trunks, roots, leaves, and fruits, bear to the wants of man and other animals, in supplying food, clothing, and materials for constructing habitations—the gums and resinous substances they exude—the odors they exhale—the variety of colors they exhibit—the vast diversity of forms in which they appear—and the beauty and variety which they spread over the whole face of nature.

The *mineral kingdom* would next require to be surveyed. We would inquire into the facts which have been ascertained respecting the *earthy*, *saline*, *inflammable*, and *metallic* substances, which are found on the surface and in the bowels of the earth—their specific and distinguishing characters—the elementary principles, or simple substances, of which they are composed—the regions of the earth where the respective minerals most frequently abound—and the ends which they are designed to accomplish in the constitution of the globe. We would consider, more particularly, the various metals, such as iron, copper, lead, tin, gold silver, bismuth, zinc, etc., in reference to the substances with which they are united in their native ores—the changes produced upon them by the action of oxygen and the different acids—their combustibility—their combination with phosphorus, sulphur, and carbon—the various compounds into which they may be formed—their important uses in the arts which minister to the comfort and embellishment of human life—their relation to the multifarious necessities of man—and the wisdom and goodness of the Creator, as displayed in their arrangement in the bowels of the earth, and in the admirable properties of which they are possessed. In these details, the natural history of *Iron* would hold a prominent place. In point of *utility*, it claims the highest rank in the class of metals, and is intrinsically more valuable than gold and silver, and all the diamonds of the East. There is scarcely a mineral substance in the whole compass of nature which affords a more striking instance of the beneficial and harmonious adaptation of things in the universal system. We would, therefore, consider it in reference to its vast abundance in all parts of the world—the numerous substances into which it enters into combination—its magnetical property—its capability of being fused and welded—the numerous useful utensils it has been the means of producing—its agency in carrying forward improvements in art and science, in the civilization of barbarous tribes, and in promoting the progress of the human mind; and the aids which it affords to the Christian missionary in heathen lands.

---

* The term *science*, in its most general and extensive sense, signifies *knowledge*, particularly that species of knowledge which is acquired by the exertion of the human faculties. In a more restricted sense, it denotes a *systematic* species of knowledge which consists of rule and order, such as Mathematics, Astronomy, Natural Philosophy, etc.—In the discussions contained in this work, it is used in its most general sense, as denoting the various departments of human knowledge; in which sense, history, both natural, civil, and sacred, may be termed *science*.

Having surveyed the inanimate parts of the terraqueous globe, and its appendages, we might next direct our attention to the animated tribes with which it is peopled. Beginning at *Man*, the head of the animal creation, we would detail the principal facts which have been ascertained respecting his structure and organical functions—the muscular movements of the human body, the system of bones, nerves, veins, and arteries; the process of respiration; and the organs of vision, hearing, smelling, tasting, and feeling, by which he holds a correspondence with the material world—the modifications which appear in his corporeal frame, and in his mental faculties, during the periods of infancy, puberty, manhood, and old age—the causes and phenomena of sleep and dreaming—the varieties of the human race, in respect of color, stature, and features—the deviations from the ordinary course of nature, which occasionally occur, in the case of monsters, dwarfs, and giants—the moral and intellectual faculties—and those distinguishing characteristics which prove the superiority of man over the other tribes of animated nature.

The inferior ranks of the animal creation would next demand our attention. We would take a survey of the numerous tribes of *Quadrupeds*, *Birds*, *Fishes*, *Serpents*, *Lizards*, and *Insects*, in reference to the characteristic marks by which the different species are distinguished,—their food, and habitations—the different modes in which they display their architective faculty, in constructing places of abode for shelter and protection—the clothing with which they are furnished—their sagacity in finding out the proper means for subsistence and self-preservation—their hostilities—their artifices in catching their prey, and escaping their enemies—their modes of propagation—their transformations from one state and form to another—their migrations to different countries and climates—their various instincts—their care in rearing and protecting their young—their passions, mental characters, and social dispositions—their language or modes of communication with each other—their capacities for instruction and improvement—their different powers of locomotion—the adaptation of all their organs to the purposes for which they seem intended—the indications they give of being possessed of moral dispositions and rational powers—their different periods of longevity, and the ends which they are intended to subserve in the system of nature. Along with these details, certain views might be exhibited of the various forms of sensitive life, and modes of existence, which obtain in those numerous species of animals which are invisible to the naked eye, and which the microscope discovers in almost every department of nature.

Having surveyed the objects which compose our sublunary system, we would next direct our view to the regions of the sky, and contemplate the facts which have been discovered in relation to the celestial orbs. We would first attend to the *apparent* motion of the sun, the different points of the horizon at which it seems to rise and set, and the different degrees of elevation to which it arrives, at different seasons of the year,—the different aspects it presents as viewed from different parts of the earth's surface, and the different lengths of days and nights, in different parts of the world. We would next attend to the varied phases of the moon—the direct and retrograde motions of the planets—the apparent diurnal motion of the whole celestial sphere, from east to west—and the different clusters of stars which are seen in our nocturnal sky, at different seasons of the year. We would next consider the deductions which science has made, respecting the order and arrangement of the planets which compose the solar system—their distances from the sun, and from the earth—their magnitudes—the periods of their diurnal and annual revolutions—the secondary planets, or moons, which accompany them—their eclipses—the various phenomena which their surfaces present when viewed through telescopes—the physical influence which some of them produce on the surface of our globe—and the singular appearance of those bodies called *Comets*, which occasionally visit this part of our system. We would, in the next place, extend our views to the starry regions, and consider the number of stars which present themselves to the naked eye—the immensely greater numbers which are discovered by telescopes—the systems into which they appear to be arranged—the facts which have been ascertained respecting *new* stars—double and treble stars—stars once visible, which have now disappeared from the heavens—variable stars, whose luster is increased and diminished at different periods of time—and the structure and position of the many hundreds of *Nebulæ*, or starry systems, which appear to be dispersed throughout the immensity of creation.

All the particulars now stated, and many others which might have been specified—*considered simply as facts* which exist in the system of Nature—form the appropriate and legitimate objects of Natural History, and demand the serious attention of every rational intelligence, that wishes to trace the perfections and agency of the Almighty Creator. To investigate the *causes* of the diversified phenomena which the material world exhibits, and the principles and modes by which many of the facts now alluded to are ascertained, is the peculiar province of Natural Philosophy, Chemistry, and the Mathematical Sciences.

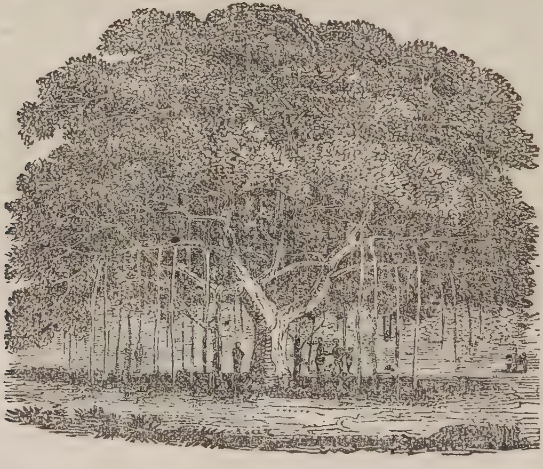
Amidst so vast a variety of objects as Natural History presents, it is difficult to fix on any particular facts, as specimens of the interesting nature of this department of knowledge, without going beyond the limits to which I am necessarily confined in this volume. I shall content myself with a description of two objects, which have a reference chiefly to the vegetable kingdom. The first of these is

THE BANIAN TREE.—"This Tree, which is also called the *Burr tree*, or the *Indian Fig*, is one of the most curious and beautiful of Nature's productions, in the genial climate of India, where she sports with the greatest variety and profusion. Each tree is in itself a grove; and some of them are of an amazing size and extent, and, contrary to most other animal and vegetable productions, seem to be exempted from decay. Every branch from the main body throws out its own roots; at first, in small tender fibers, several yards from the ground; these continually grow thicker, until, by a gradual descent, they reach the surface, and there, striking in, they increase to large trunks, and become parent trees, shooting out new branches from the tops. These in time suspend their roots, and, receiving nourishment from the earth, swell into trunks, and shoot forth other branches; thus continuing in a state of progression, so long as the earth, the first parent of them all, contributes her sustenance. A Banian tree, with many trunks, forms the most beautiful walks, vistas, and cool recesses, that can be imagined. The leaves are large, soft, and of a lively green, about six inches in length; the fruit is a small fig, when ripe, of a bright scarlet, affording sustenance to monkeys, squirrels, peacocks, and birds of various kinds, which dwell among the branches.

"The Hindoos are peculiarly fond of the Banian tree; they consider its long duration, its outstretching arms, and its overshadowing beneficence, as emblems of the Deity, and almost pay it divine honors. The Brahmins, who thus 'find a fane in every sacred grove,' spend much of their time in religious solitude, under the shade of the Banian tree; they plant it near their temples or pagodas: and in those villages where there is no structure erected for public worship, they place an image under one of these trees, and there perform a morning and evening sacrifice. The natives of all castes and tribes are fond of recreating in the cool recesses, beautiful walks, and lovely vistas of this umbrageous canopy, impervious to the hottest beams of a tropical sun. It is recorded that one of these trees shaded all the town of Fort St. David and Gombroon. These are the trees under which a sect of naked philosophers, called Gymnosophists, assembled in Arian's days, and this historian of ancient Greece presents a true picture of the Modern Hindoos. 'In winter,' he says, 'the Gymnosophists enjoy the benefit of the sun's rays in the open air; and, in summer, when the heat becomes excessive, they pass their time in cool and moist places, under large trees, which, according to the accounts of Nearchus, cover a circumference of *five acres*, and extend their branches so far, than *ten thousand men* may easily find shelter under them.'

"On the banks of the river Narbudda, in the province of Guzzerat, is a Banian tree, supposed, by some persons to be the one described by Nearchus, who commanded the fleet of Alexander the Great, and certainly not inferior to it. It is distinguished by the name of Cubbeer Burr, which was given it in honor of a famous saint. Forbes, in his 'Oriental Memoirs,' when speaking of the age of such trees, states that he smoked his hookha under the very Banian beneath which part of Alexander's cavalry took shelter. High floods have, at various times, swept away a considerable part of this extraordinary tree; but what still remains is nearly *two thousand feet* in circumference, measured round the principal stems; the overhanging branches, not yet struck down, cover a much larger space; and under it grow a number of custard-apple and other fruit trees. The large trunks of this single tree amount to *three hundred and fifty;* and the smaller ones exceed three thousand; every one of these is constantly sending forth branches and hanging roots to form other trunks, and become the parents of a future progeny. The Cubbeer Burr is famed throughout Hindostan, not only on account of its great extent, but also of its surpassing beauty. The Indian armies generally encamp around it; and at stated seasons, solemn Jatarras, or Hindoo festivals, to which thousands of votaries repair from every part of the Mogul

Fig. 12.



empire, are there celebrated. It is said that seven thousand persons find ample room to repose under its shade. It has long been the custom of the British residents in India, on their hunting and shooting parties, to form extensive encampments, and spend weeks together, under this delightful and magnificent pavilion, which affords a shelter to all travelers, particularly to the religious tribes of the Hindoos. It is generally filled with green wood-pigeons, doves, peacocks, and a variety of feathered songsters—with monkeys, which both divert the spectator by their antic tricks, and interest him by the parental affection they display to their young offspring, in teaching them to select their food, and to exert themselves in jumping from bough to bough,—and is shaded by bats of a large size, many of them measuring upward of six feet from the extremity of one wing to the other. This tree affords not only shelter, but also sustenance, to all its inhabitants, being covered, amid its bright foliage, with small figs, of a rich scarlet, on which they all regale with as much delight as the lords of creation on their more costly fare, in their parties of pleasure."

The preceding figure will convey a general, though imperfect, idea of this singular tree, and of the manner in which the branches from the main body throw out their shoots, and form the numerous vista. which are found under its shade.

This tree, which is doubtless one of the most singular and magnificent objects in the vegetable kingdom, appears to be a world in miniature, in which thousands, both of human beings, and of the inferior tribes that traverse the earth and the air, may find ample accommodation and subsistence. What a striking contrast does it present to the forests of trees, or mushroons, which are perceived by the help of the microscope, in a piece of *moldiness*--every plant of which is several hundreds of times smaller than the point of a fine needle! Yet both are the effects of the agency of the same All-wise and Omnipotent Being. And what an immense variety of gradations is to be found in the vegetable world, between these two extremes—every part of the vast interval being filled up with flowers, herbs, shrubs, and trees, of every color, form, and size, and in such vast multitudes and profusion that no man can number them!

An object which approximates in a certain degree to the one now described, is mentioned in "Staunton's Account of Macartney's Embassy to China," p. 70. It is called by Botanists, *Adansonia*, and is also known by the name of the *Monkey Bread Tree*, and was discovered in the Island of St. Jago. "The circumference or girth of the base was 56 feet, which soon divided into two vast branches, the one in a perpendicular direction, whose periphery, or girth, was 42 feet, the other 26. Another, of the same species, stood near it, whose single trunk, girthing 38 feet, was scarcely noticed."

The only other specimen I shall exhibit to the reader, has a relation both to the animal and to the vegetable kingdom It is well known that the examination of flowers, and vegetables, of every description, by the microscope, opens a new and interesting field of wonders to the inquiring naturalist. Sir JOHN HILL has given the following curious account of what appeared on his examining a carnation:—

"The principal flower in an elegant bouquet was a carnation: the fragrance of this led me to enjoy it frequently and near. The sense of smelling was not the only one affected on these occasions: while that was satiated with the powerful sweet, the ear was constantly attacked by an extremely soft, but agreeable murmuring sound. It was easy to know, that some animal within the covert must be the musician, and that the little noise must come from some little creature suited to produce it. I instantly distended the lower part of the flower, and placing it in a full light, could discover troops of little insects frisking, with wild jollity, among the narrow pedestals that supported its leaves, and the little threads that occupied its center. What a fragrant world for their habitation! What a perfect security from all annoyance, in the dusky husk that surrounded the scene of action! Adapting a microscope to take in, at one view, the whole base of the flower, I gave myself an opportunity of contemplating what they were about, and this for many days together, without giving them the least disturbance. Thus, I could discover their economy, their passions, and their enjoyments. The microscope, on this occasion, had given what nature seemed to have denied to the objects of contemplation. The base of the flower extended itself, under its influence, to a vast plain; the slender stems of the leaves became trunks of so many stately cedars; the threads in the middle seemed columns of massy structure, supporting at the top their several ornaments; and the narrow spaces between were enlarged in walks, parterres, and terraces. On the polished bottoms of these, brighter than Parian marble, walked in pairs, alone or in larger companies, the winged inhabitants; these, from little dusky flies, for such only the naked eye would have shown them, were raised to glorious glittering animals, stained with living purple, and with a glossy gold, that would have made all the labors of the loom contemptible in the comparison.—I could, at leisure, as they walked together, admire their elegant limbs, their velvet shoulders, and their silken wings; their backs vieing with the empyrean in its blue; and their eyes, each formed of a thousand others, out-glittering the little planes on a brilliant; above description, and too great almost for admiration. I could observe them here singling out their favorite females; courting them with the music of their buzzing wings, with little songs, formed for their little organs, leading them from walk to walk, among the perfumed shades, and pointing out to their taste, the drop of liquid nectar, just bursting from some vein within the living trunk—here were the perfumed groves, the more than mystic shades of the poet's fancy realized. Here the happy lovers spent their days in joyful dalliance, or in the triumph of their little hearts, skipped after one another, from stem to stem, among the painted trees, or winged their short flight to the close shadow of some broader leaf, to revel undisturbed in the lights of all felicity."

This picture of the splendor and felicity of insect life, may, to certain readers, appear somewhat overcharged. But those who have been much in the habit of contemplating the beauties of the animal and vegetable world, through microscopes, can easily enter into all the views which are here described. I have selected this example, for the purpose of illustrating the unbounded goodness of the Creator, in the vast profusion of enjoyment he has communicated even to the lowest tribes of animal existence, and as a specimen of those invisible worlds which exist beyond the range of our natural vision. For it appears, that there is a gradation of worlds downward, as well as upward. However small our globe may appear when compared with the sun, and with the immensity of starry systems which lie dispersed through the infinity of space, there are worlds filled with myriads of living beings, which, in point of size and extent, bear as small a proportion to the earth, as the earth bears to the vast assemblage of the celestial worlds. A single flower, a leaf, or a drop of water, may appear as large, and as diversified in its structure, to some of the beings which inhabit it, as the whole earth appears to the view of man: and a thousand scenes of magnificence and beauty may be presented to their sight, of which no distinct conception can be formed by the human mind. The many thousands of transparent globes, of which their eyes are composed, may magnify and multiply the objects around them without end, so that an object scarcely visible to the eye of man, may appear to them as a vast extended universe.

"Having examined," says St. Pierre, "one day, by a microscope, the flowers of thyme, I distinguished in them, with equal surprise and delight, superb flagons with long necks, of a substance resembling the amethyst, from the gullets of which seemed to flow ingots of liquid gold. I have never made observations of the *corolla*, simply of the smallest flower, without finding it composed of an admirable substance, half transparent, studded with brilliants, and shining in the most lively colors. The beings which live under a reflex thus enriched must have ideas very different from ours, of light, and of the other phenomena of nature. A drop of dew, filtering in the capillary and transparent tubes of a plant, presents to them thousands of cascades; the same drop fixed as a wave on the extremity of one of its prickles, —an ocean without a shore; evaporated into air, a vast aerial sea.—It is credible, then, from analogy, that there are animals feeding on the leaves of plants, like the cattle in our meadows and on our mountains, which repose under the shade of a down imperceptible to the naked eye, and which, from goblets formed like so many suns, quaff nectar of the color of gold and silver."

Thus it appears that the universe extends to infinity on either hand; and that wherever matter exists, from the ponderous globes of heaven down to the invisible atom, there the Almighty Creator has prepared habitations for countless orders of existence, from the seraph to the animalcule, in order to demonstrate his boundless beneficence, and the infinite variety of modes by which he can diffuse happiness through the universal system.

"How sweet to muse upon His skill, display'd—
Infinite skill!—in all that he has made,
To trace in Nature's most minute design,
The signature and stamp of Power Divine;
Contrivance exquisite, express'd with ease,
Where unassisted sight no beauty sees;
The shapely limb and lubricated joint,
Within the small dimensions of a point;
Muscle and nerve miraculously spun,
His mighty work; who speaks and it is done:
Th' Invisible in things scarce seen reveal'd;
To whom an atom is an ample field!"—Cowper.

With regard to the *religious* tendency of the study of Natural History, it may be remarked, that as all the objects which it embraces are the *workmanship of God*, the delineations and descriptions of the Natural Historian must be considered as "the history of the operations of the Creator;" or, in other words, so far as the science extends, "the history of the Creator himself;" for the marks of his incessant agency, his power, wisdom, and beneficence, are impressed on every object, however minute, throughout the three kingdoms of nature, and throughout every region of earth, air, and sky. As the Deity is invisible to mortal eyes, and cannot be directly contemplated by finite minds, without some material medium of communication, there are but two mediums with which we are acquainted by which we can attain a knowledge of his nature and perfections. These are, either the *facts* which have occurred in the course of his providential dispensations toward our race, since the commencement of time, and the moral truths connected with them—or the facts which are displayed in the economy of nature. The first class of facts is recorded in the Sacred History, and in the Annals of Nations; the second class is exhibited in the diversified objects and motions which appear throughout the system of the visible universe. The one may be termed the *Moral History*, and the other the *Natural History* of the operations of the Creator. It is obviously incumbent on every rational being to contemplate the Creator through both these mediums, for each of them conveys its distinct and peculiar revelations; and, consequently, our perception of Deity through the one medium does not supersede the necessity of our contemplating him through the other While, therefore, it is our duty to contemplate the perfections, the providence, and the agency of God, as displayed in the Scripture-revelation, it is also incumbent upon us to trace his attributes in the system of Nature, in order that we may be enabled to contemplate the Eternal Jehovah, *in every variety of aspect* in which he has been pleased to exhibit himself in the universe he has formed.

The visible creation may be considered as a permanent and sensible manifestation of Deity; intended every moment to present to our view the unceasing energies of Him "in whom we live and move." And if the train of our thoughts were directed in its proper channel, we would perceive God in every object and in every movement; we would behold him operating in the whirlwind and in the storm; in the subterraneous cavern and in the depths of the ocean; in the gentle rain and the refreshing breeze; in the rainbow, the fiery meteor, and the lightning's flash; in the splendors of the sun and the majestic movements of the heavens; in the frisking of the lambs, the songs of birds, and the buzz of insects; in the circulation of our blood, the movements of our joints, the motion of our eye-balls, and in the rays of light which are continually darting from surrounding objects, for the purposes of vision. For these and ten thousand other agencies in the system of nature, are nothing else but the voice of Deity, proclaiming to the sons of men, in silent but emphatic language, "Stand still, and consider the wonderful works of God."

If, then, it be admitted that the study of Nature is the study of the Creator—to overlook the grand and beautiful scenery with which we are surrounded, or to undervalue anything which Infinite Wisdom has formed, is to overlook and contemn the Creator himself. Whatever God has thought proper to create, and to present to our view in the visible world, it becomes man to study and contemplate, that from thence he may derive motives to excite him to the exercise of reverence and adoration, of gratitude and praise. In so far as any individual is unacquainted with the various facts of the history of nature, in so far does he remain ignorant of the manifestations of Deity; for every object on the theater of the universe exhibits his character and designs in a different point of view. He who sees God only as he displays himself in his operations on the earth, but has never contemplated the firmament with the eye of reason, must be unacquainted with those amazing energies of eternal Power, which are displayed in the stupendous fabric and movements of the orbs of heaven. He who sees God only in the general appearances of nature, but neglects to penetrate into his minute operations, must remain ignorant of those astonishing manifestations of Divine wisdom and skill, which appear in the contrivances, adaptations, and functions of the animal and the vegetable kingdoms. For the more we know of the work, the more accurate and comprehensive will be our views of the Intelligence by whom it was designed; and the farther we carry our investigations of the works of God, the more admirable and astonishing will his plans and perfections appear.

In short, a devout contemplation of the works of nature tends to ennoble the human soul, and to purify and exalt the affections. It inspires the mind with a relish for the beauty, the harmony, and order, which subsist in the universe around us—it elevates the soul to the love and admiration of that Being who is the Author of all our comforts and of all that is sublime and beneficent in creation, and excites us to join with all holy beings in a chorus of praise to the God and Father of all. For they

> "Whom nature's works can charm, with God himself
> Hold converse, grow familiar day by day
> With his conceptions, act upon his plan,
> And form to his the relish of their souls."

The man who surveys the vast field of nature with the eye of reason and devotion, will not only acquire a more comprehensive view of that illimitable power which organized the universe, but will find his sources of enjoyment continually increased, and will feel an ardent desire after that glorious world, where the vail which now hides from our sight some of the grandest manifestations of Deity will be withdrawn, and the wonders of Omnipotence be displayed in all their splendor and perfection.

In conformity with these sentiments, we find the inspired writers, in numerous instances, calling our attention to the wonders of creating power and wisdom. In one of the first speeches in which the Almighty is introduced as addressing the sons of men, and the longest one in the Bible,[*] our attention is exclusively directed to the subjects of Natural History;—the whole address having a reference to the economy of Divine Wisdom in the arrangement of the world at its first creation—the wonders of the ocean, and of light and darkness—the phenomena of thunder and lightning, rain, hail, snow, frost, and other meteors in the atmosphere—the intellectual faculties of man, and the economy and instincts of quadrupeds, birds, fishes, and other tribes of animated existence. Indeed, the greater part of the sublime descriptions contained in the book of Job has a direct reference to the agency of God in the material creation, and to the course of his providence in relation to the different characters of men; and the reasonings of the different speakers in that sacred drama, proceed on the supposition, that their auditors were intimately acquainted with the varied appearances of nature, and their tendency to exhibit the character and perfections of the Omnipotent Creator. We find the Psalmist, in Psalm civ, employed in a devout description of similar objects, from the contemplation of which his mind is raised to adoring views of their Almighty Author—and, from the whole of his survey, he deduces the following conclusions:—"How manifold are thy works, O Lord! *In wisdom* thou hast made them all! The earth is full of thy riches; so is this great and wide sea, wherein are things creeping innumerable, both small and great beasts. The glory of the Lord shall endure forever; the Lord shall rejoice in all his works.[*] I will sing unto the Lord as long as I live; I will sing praises to my God while I have my being."

But in order to enter into the spirit of such sublime reflections, we must not content ourselves with a superficial and cursory view of the objects and operations of nature,—we must not think it sufficient to acquiesce in such vague propositions as these: "The glory of God is seen in every blade of grass, and every drop of water; all nature is full of wonders, from the dust of the earth to the stars of the firmament." We must study the works of creation with ardor, survey them with minute attention, and endeavor to acquire a *specific* and *comprehensive* knowledge of the Creator's designs. We must endeavor to acquire a knowledge of the particular modes, circumstances, contexture, configurations, adaptations, structure, functions, and relations of those objects in which benevolence and design conspicuously appear—in the animal and the vegetable world, in the ocean, the atmosphere, and the heavens; that the mind may be enabled to draw the conclusion with full conviction and intelligence—"*In wisdom thou hast made them all!*" The pointed interrogatories which Jehovah addressed to Job, evidently imply that Job had previously acquired an intimate acquaintance with the works of nature. It seems to be taken for granted, as a matter of course, that he had made himself acquainted with the general range of facts in the visible creation; and the intention of the several questions presented to his consideration evidently was, to impress him with a sense of his own impotency, and to lead him to the investigation of the wonders of Creating Power, which he had formerly overlooked. The conclusion which the Psalmist draws respecting the *Wisdom* displayed throughout all the works of God, plainly intimates, that he had made the different parts of nature the subject of minute examination and of deep reflection; otherwise he could not have rationally deduced his conclusion, or felt those emotions which filled his mind with the pious raptures so beautifully expressed in that hymn of praise to the Creator of the world.

We have therefore reason to believe, from these and other instances, that pious men, "in the days of old," were much more accustomed than modern Christians to contemplate and admire the visible works of the Lord; and it is surely much to be regretted, that we, who enjoy so many superior means of information, and who have access to the brilliant discoveries of later and more enlightened times, should manifest so much disregard to "the works of Jehovah, and the operations of his hands." To enable the common mass of Christians to enter into the spirit of this delightful study and *Christian duty*, should, therefore, be one object of those periodical and other religious works which are put into their hands; so that they may be enabled, with vigor and intelligence, to form the pious resolution of Asaph, "I will meditate on all thy works, O Lord! and talk of thy doings." "I will utter abundantly the memory of thy great goodness, and tell of all thy wondrous works."

---

[*] Job, chaps. xxxviii, xxxix, xl, xli.

[*] The *glory* of the Lord, in this passage, denotes the display of his perfections in the material universe; and the declaration of the inspired writer plainly intimates, that this display will continue *forever*, and will remain as an object of unceasing contemplation to all intelligences, and as an eternal monument of his Power and Wisdom. For although the earth and the aerial heavens will be changed at the close of that dispensation of Providence which respects our world, yet the general frame of the universe, in its other parts, will remain substantially the same; and not only so, but will, in all probability, be perpetually increasing in magnitude and grandeur. And the change which will be effected in respect to the terraqueous globe and its appendages will be such that Jehovah will have reason to "rejoice" in this, as well as in all his other works.

GEOGRAPHY.

The next department of knowledge I shall notice is the science of Geography.

The object of this science is, to describe the world we inhabit, in reference to the continents, islands, mountains, oceans, seas, rivers, empires, and kingdoms with which it is diversified, together with the manners, customs, and religion of the different tribes which people its surface.

In order to form an accurate conception of the relative positions of objects on the surface of the earth, and to enter, with intelligence, on the study of this subject, it is requisite, first of all, to have an accurate idea of its *figure and magnitude.* For a long series of ages, it was supposed, by the bulk of mankind, that the surface of the earth was nearly a plane, indefinitely extended, and bounded on all sides by the sky. Lactantius, and several of the Fathers of the Christian Church, strenuously argued, that the earth was extended infinitely downward, and established upon several foundations. The ancient philosopher Heraclitus is said to have believed, that the earth was of the shape of a skiff or canoe, very much hollowed; and the philosopher Leucippus supposed it to be of the form of a cylinder or a drum. It is only within the period of the last three hundred years that the true figure of the earth has been accurately ascertained. This figure is now found to be that of an oblate spheroid, nearly approaching to the shape of a globe or sphere. To have asserted this opinion several ages ago would have been considered as a heresy in religion, and would have subjected its abettors to the anathemas of the Church, and even to the peril of their lives. Historians inform us, that the learned Spigelius, bishop of Upsal, in Sweden, suffered martyrdom at the stake, in defense of the doctrine of the *Antipodes;* and we know that, for asserting the motion of the earth, the celebrated philosopher Galileo was immured in a dungeon, and condemned by an assembly of Cardinals, to all the horrors of perpetual imprisonment. The doctrine he maintained, and which is now universally received by every one acquainted with the subject, was declared by those arrogant ecclesiastics to be "a proposition absurd in its very nature, false in philosophy, heretical in religion, and contrary to the Holy Scriptures." Such are some of the horrible and pernicious consequences which flow from ignorance of the phenomena of nature, and of those laws by which the Almighty governs the universe he has formed; and which prove it to be a Christian duty for every rational being to study the order and economy of the visible world.

That the earth is nearly of a globular figure is proved by the following considerations:—1. When we stand on the sea-shore, while the sea is perfectly calm, we perceive that the surface of the water is not quite plane, but convex or rounded: and if we are on one side of an arm of the sea, as the Frith of Forth, and with our eyes near the water, look toward the opposite coast, we shall plainly see the water elevated between our eyes and the opposite shore, so as to prevent our seeing the land near the edge of the water. The same experiment may be made on any portion of still water, of a mile or two in extent, when its convexity will be perceived by the eye. A little boat, for instance, may be perceived by a man who is any hight above the water, but if he stoops down and lays his eye near the surface, he will find that the fluid appears to rise, and intercept the view of the boat. 2. If we take our station on the sea shore, and view the ships leaving the coast, in any direction—as they retire from our view, we may perceive the masts and rigging of the vessels when the hulls are out of sight, and, as it were, sunk on the water. On the other hand, when a ship is approaching the shore, the first part of her that is seen is the topmast; as she approaches nearer, the sails become visible, and, last of all, the hull comes gradually into view.* The reason of such appearances obviously is, that the round or convex surface of the water interposes between our eye and the body of the ship, when she has reached a certain distance, while, at the same time, the sails and topmast, from their great elevation, may be still in view. To the same cause it is owing, that the higher the eye is placed, the more extensive is the prospect; and hence it is common for sailors to climb to the top of masts, in order to discover land or ships at a distance. The contrary of all this would take place, if the earth and waters were an extended plane. When a ship came within view, the hull would first make its appearance, being the largest object, next the sails, and last of all the topmast. These considerations, which hold true in all parts of the world, prove to a certainty, that the mass of the ocean is of a globular form; and if the ocean be a portion of a sphere, it follows, that the *land* also is of the same general figure; for no portion of the earth's surface is elevated above four or five miles above the level of the ocean. 3. That the earth is round from north to south, appears from the following circumstances:—When we travel a considerable distance from north to south, or from south to north, a number of new stars successively appear in the heavens, in the quarter to which we are advancing, and many of those in the opposite quarter gradually disappear, which would not happen if the earth were a plane in that direction. 4. That the earth is round from east to west, appears from actual experiment; for many navigators, by sailing in a westerly direction, have gone quite round it, from east to west; and were it not for the frozen seas, within the polar regions, which interrupt navigation in those directions, it would, long ere now, have been circumnavigated from north to south. 5. All these proofs are confirmed and illustrated by eclipses of the moon, which present an *ocular demonstration* of the earth's rotundity. An eclipse of the moon is caused by the intervention of the body of the earth between the sun and the moon; in which case, the shadow of the earth falls upon the moon. This shadow is found in all cases, and in every position of the earth, to be of a *circular* figure; which incontrovertibly proves that the whole mass of land and water, of which the earth is composed, is nearly of a globular form. The mountains and vales which diversify its surface, detract little or nothing from its globular shape; for they bear no more proportion to its whole bulk than a few grains of sand to a common terrestrial globe; the highest mountains on its surface being little more than the two-thousandth part of its diameter. Some of the mountains on the surface of the moon are higher than those on the earth, and yet that body appears, both to the naked eye and through telescopes, of a spherical figure.

---

* In order to make such observations to advantage, the observer's eye should be, as near as possible, on a level with the sea, and he should use a telescope to enable him to perceive more distinctly the upper parts of the vessel.

To some readers, the discovery of the true figure of the earth may appear as a matter of very trivial importance in religion. I hesitate not, however, to affirm, that it constitutes a most important fact in the history of Divine Providence. Had not this discovery been made, it is probable that the vast continent of America might yet have remained undiscovered; for Columbus, who first discovered that new world, had learned, contrary to the general opinion of those times, that the earth was of a spherical figure; and, from the maps then existing, he began to conjecture that the nearest way of sailing to the East Indies would be to sail westward. And although he missed the object of his research, he was the means of laying open to view a vast and unknown region of the earth, destined, in due time, to receive from the eastern world the blessings of knowledge, civilization, and religion. On the knowledge of the spherical figure of the earth, the art of navigation in a great measure depends; and all the voyages of discovery which have been made in later years, were undertaken in consequence of the knowledge of this fact. Had mankind remained unacquainted with this discovery, the circumnavigation of the globe would never have been attempted—vast portions of the habitable world would have remained unknown and unexplored—no regular intercourse would have been maintained between the various tribes of the human race, and consequently, the blessings of Divine Revelation could never have been communicated to the greater part of the Gentile world. Beside, the knowledge of the true figure and magnitude of our sublunary world forms the groundwork of all the sublime discoveries which have hitherto been made in the regions of the firmament. For its diameter forms the *base-line* of those triangles by which the distances and magnitudes of the celestial globes have been determined,* without a knowledge of the extent of which, the important results which have been deduced respecting the system of the universe, could not have been ascertained, and consequently, our views of the grandeur and omnipotence of the Deity, and of the magnificence and extent of his dominions, must have been much more circumscribed than they now are. Such is the intimate connection that subsists between every part of the chain of Divine dispensations, that if any one link had been either broken or dissolved, the state of things, in the moral and intellectual world, would have been very different from what it now is; and the plans of Providence, for accomplishing the renovation and improvement of mankind, would have been either partially or totally frustrated.

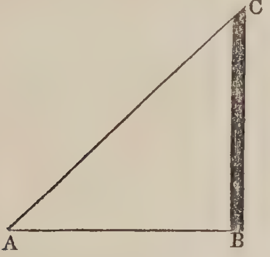
With regard to the *magnitude* of the earth—I have already stated the mode by which we may acquire the most accurate and comprehensive conception of this particular, in the course of the illustrations which were given of the Omnipotence of Deity—(pp. 15–17). It is necessary here only to remark that, according to the latest computations, the diameter of the earth is about 7930 miles, and its circumference 24,912 miles; and consequently, the whole surface of the land and water it contains comprehends an area of 197,552,160 miles. The proportion of land and water on its surface cannot be very accurately ascertained; but it is quite evident, from an inspection of a map of the world, that the water occupies at

---

* In order that the general reader may understand what is meant by "the diameter of the earth forming the *base-line* of those triangles by which the distances, etc. of the heavenly bodies are measured," it may not be unnecessary to state the following explanations.

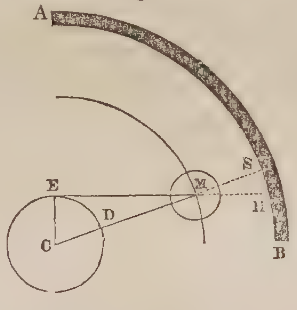
In any triangle, as A B C, if the length of the side A B be known, and likewise the quantity of the angles at A and B, or the number of degrees or minutes they subtend, be ascertained, we can find the length of the sides A C and B C. If A B represent a horizontal plane, 100 feet in extent, and C B a tower whose hight we wish to determine, and if, with a quadrant, we find the angle at A, or C A B, to be 43 degrees; then by an easy trigonometrical process—Radius: is to the tangent of A, 43° : : as the side A B, 100 feet : is to the hight of the tower C B, which, in this case, will be found to be 93¼ feet.

Fig. 13.



It is on this general principle that the distances and magnitudes of the celestial bodies are determined. But, in all cases where we wish to ascertain the dimensions of the different parts of a triangle—*one side*, at least, must be given, along with two angles, otherwise the length of the different sides of the triangle cannot be determined.—Now, in measuring the distance of a heavenly body, such as the Moon, the *diameter* or *semidiameter* of the earth is the *known side* of the triangle by which such a distance is to be found. In Fig. 14, let E C represent the Earth, M the Moon, and A B a portion of the starry firmament. If a spectator at the earth's surface at E view the moon in the horizon, it will appear in the line E M, among the stars at H. But, if viewed from the center of the earth at C or from the surface at D, it will appear in the line C D M, among the stars at S. The difference of position in which the moon is seen, as viewed from the surface of the earth E, and the center C, is called the moon's horizontal parallax, or the arc S H which is subtended by the angle S M H, which is equal to the angle E M C. In determining the distance of the moon therefore, we must first find, by observation, the horizontal parallax, or, in other words, the angle E M C; and the side E C, or the semidiameter of the earth being known to be about 4000 miles in extent, forms the *base-line* of the triangle E M C, and hence the other sides of the triangle E M and C M, or the distance of the moon from the earth, can be found by an easy calculation.

Fig. 14.



From what has been now stated it will appear that, were we ignorant of the figure and magnitude of the earth, we could not ascertain the distance of the moon or any other celestial body. In the above explanation I have merely stated the *principle* on which astronomers proceed in measuring the distances of bodies in the heavens, without descending into details. For a more particular explanation and illustration of this subject, the reader is referred to the author's work entitled "Celestial Scenery," chap. vii, where the subject is pretty fully and popularly treated.

least two-thirds of its surface, and of course the land cannot occupy more than one-third. Supposing it to be only one-fourth of the earth's surface, it will contain 49,388,040 square miles, which is considerably more than what is stated in most of our late systems of Geography; in some of which the extent of the land is rated at 39 millions, and in others so low as 30 millions of square miles—the former of which statements being less than one-fifth, and the latter less than one-sixth of the surface of the globe. But it is quite obvious that the extent of the land cannot be less than one-fourth of the area of the globe, and must, therefore, comprehend at least about 50 millions of square miles. And if a large arctic continent, eleven hundred leagues in length, exist around the North Pole, as some French philosophers infer, from Captain Parry's late discoveries*—the quantity of land on the terraqueous globe will be much greater than what has now been stated.

General Divisions of the Earth.—The surface of the earth is divided, from north to south, by two bands of earth, and two of water. The first band of earth is the ancient or Eastern Continent, comprehending Europe, Asia, and Africa; the greatest length of which is found to be in a line beginning on the east point of the northern part of Tartary, and extending from thence to the Cape of Good Hope, which measures about 10,000 miles, in a direction nearly from north-east to south-west; but if measured according to the meridians, or from north to south, it extends only 7500 miles, from the northernmost cape in Lapland to the Cape of Good Hope. This vast body of land contains about 36 millions of square miles, forming nearly one-fifth of the whole surface of the globe. The other band of earth is what is commonly called the New Continent, which comprehends North and South America. Its greatest length lies in a line beginning at the south of the river Plata, passing through the island of Jamaica, and terminating beyond Hudson's Bay; and it measures about 8000 miles. This body of land contains about 14 millions of square miles, or somewhat more than a third of the Old Continent.

It may not be improper here to remark, that the two lines now mentioned, which measure the greatest length of the two continents, divide them into two equal parts, so that an equal portion of land lies on each side of these lines, and that each of the lines has an inclination of about 30 degrees to the equator, but in opposite directions; that of the old continent extending from the north-east to the south-west; and that of the new continent, from the north-west to the south-east; and that they both terminate at the same degree of northern and southern latitude. It may also be noticed, that the old and new continents are almost opposite to each other, and that the old is more extensive to the north of the equator, and the new more extensive to the south. The center of the old continent is in the 17th degree of north latitude, and the center of the new, in the 17th degree of south latitude; so that they seem to be made to counterbalance each other, in order to preserve the equability of the diurnal rotation of the earth. There is also a singular connection between the two continents, namely, that if they were divided into two parts, all four would be surrounded by the sea, were it not for the two small necks of land called the isthmuses of Suez and Panama.†

Between the two continents now mentioned lie two immense bands of water, termed the Pacific and the Atlantic oceans, whose greatest length is likewise in a direction from north to south.

Beside the two bands of earth to which I have adverted, many extensive portions of land are dispersed through the ocean, which covers the remaining part of the earth's surface; particularly the extensive regions of New Holland, which occupy a space nearly as large as the whole of Europe, and the Arctic continent, which probably exists within the North Polar regions, and which some French writers propose to designate by the name of *Boreasia*, is, in all probability, of equal extent. There are also the extensive islands of New Guinea, Borneo, Madagascar, Sumatra, Japan, Great Britain, New Zealand, Ceylon, Iceland, Cuba, Java, and thousands of others, of different dimensions, scattered through the Pacific, the Indian, and the Atlantic oceans, and which form a very considerable portion of the habitable regions of the globe.

General Features of the Earth's Surface.—In taking a general survey of the external features of the earth, the most prominent objects that strike the eye, are those huge elevations which rise above the level of its general surface, termed *Hills* and *Mountains*. These are distributed in various forms and sizes, through every portion of the continents and islands; and, running into immense chains, form a sort of connecting band to the other portions of the earth's surface. The largest mountains are generally formed into immense chains, which extend, in nearly the same direction, for several hundreds and even thousands of miles. It has been observed, by some philosophers, that the most lofty mountains form two immense ridges or belts, which, with some interruptions, extend around the whole globe in nearly the same direction. One of these ridges lies between the 45th and 55th degrees of north latitude. Beginning on the western shores of France and Spain, it extends eastward, including the Alps and the Pyrenees, in Europe, the Uralian and Altaic mountains, in Asia—extending from thence to the shores of Kamtschatka, and, after a short interruption from the sea, they rise again on the western coast of America, and terminate at Canada, near the eastern shore. It is supposed that the Chain is continued completely round the globe, through the space that is covered by the Atlantic ocean, and that the Azores, and other islands in that direction, are the only summits that are visible, until we come to the British isles. The other ridge runs along the southern hemisphere, between the 20th and 30th degrees of south latitude, of which detached portions are found in the mountains of Tucuman and of Paraguay, in South America; of Monomotapa and Caffraria, in Africa; in New Holland, New Caledonia, the New Hebrides, the Friendly, the Society, and other islands in the Pacific ocean. From these ridges flow a variety of ramifications in both hemispheres, toward the Equator and the Poles, which altogether present a magnificent scenery, which diversifies and enlivens the surface of our globe.

The highest mountains in the world, according to some late accounts published in the "Transactions of the Asiatic Society," are the *Himalaya* chain, north of Bengal, on the borders of Thibet. The highest mountain in this range is stated to be about 27,000 feet, or a little more than five miles in perpendicular hight, and is visible at the distance of 230 miles. Nineteen different mountains in this chain are stated to be above four miles in perpendicular elevation. Next to the

† See Buffon's Natural History, vol. i.

Himalayas are the Andes, in South America, which extend more than 4000 miles in length, from the province of Quito to the straits of Magellan. The highest summit of the Andes is Chimboracco, which is said to be 20,600 feet, or nearly four miles, above the level of the sea. The highest mountains in Europe are the Alps, which run through Switzerland and the north of Italy, —the Pyrenees, which separate France from Spain, and the Dofrafield, which divide Norway from Sweden. The most elevated ridges in Asia are Mount Taurus, Imaus, Caucasus, Ararat, the Uralian, the Altaian, and the Mountains of Japan, —in Africa, Mount Atlas, and the Mountains of the Moon. Some of the mountains in these ranges are found to contain immense caverns or perforations, of more than two miles in circumference, reaching from their summits to an immeasurable depth in the bowels of the earth. From these dreadful openings are frequently thrown up, to an immense hight, torrents of fire and smoke, rivers of melted metals, clouds of ashes and cinders, and sometimes red-hot stones and enormous rocks, to the distance of several miles, accompanied with thunders, lightnings, darkness, and horrid subterraneous sounds—producing the most terrible devastations through all the surrounding districts. The most noted mountains of this kind in Europe are mount Hecla, in Iceland; Etna, in Sicily; and Vesuvius, near the city of Naples, in Italy. Numbers of volcanoes are also to be found in South America, in Africa, in the islands of the Indian ocean, and in the empire of Japan.*

We who live in Great Britain where the highest mountain is little more than three quarters of a mile in perpendicular elevation, can form no adequate idea of the magnificence and awful sublimity of the mountain scenery in some of the countries now mentioned, especially when the volcano is belching forth its flames with a raging noise, and spreading terror and desolation around its base. From the tops of the lofty ridges of the Andes, the most grand and novel scenes sometimes burst upon the eye of the astonished traveler. He beholds the upper surface of the clouds far below him covering the subjacent plain, and surrounding, like a vast sea, the foot of the mountain; while the place on which he stands appears like an island in the midst of the ocean. He sees the lightnings issuing from the clouds, and hears the noise of the tempest and the thunders rolling far beneath his feet, while all is serene around him, and the blue vault of heaven appears without a cloud. At other times he contemplates the most sublime and extensive prospects—mountains ranged around him, covered with eternal snows, and surrounding, like a vast amphitheater, the plains below—rivers winding from their sources toward the ocean—cataracts dashing headlong over tremendous cliffs—enormous rocks detached from their bases, and rolling down the declivity of the mountains with a noise louder than thunder—frightful precipices impending over his head—unfathomable caverns yawning from below—and the distant volcano sending forth its bellowings, with its top enveloped in fire and smoke. Those who have studied nature on a grand scale have always been struck with admiration and astonishment at the sublime and awful exhibition of wonders which mountainous regions exhibit; and perhaps there is no *terrestrial* scene which presents, at one view, so many objects of overpowering magnitude and grandeur, and which inspires the mind with so impressive an idea of the power of that Almighty Being, who "weigheth the mountains in scales, and taketh up the isles as a very little thing."

THE OCEAN.—The ocean surrounds the earth on all sides, and penetrates into the interior parts of different countries, sometimes by large openings, and frequently by small straits. Could the eye take in this immense sheet of waters at one view, it would appear the most august object under the whole heavens. It occupies a space on the surface of the globe at least three times greater than that which is occupied by the land; comprehending an extent of 148 millions of square miles. Though the ocean, strictly speaking, is but *one* immense body of waters, extending in different directions, yet different names have been appropriated to different portions of its surface That portion of its waters which rolls between the western coast of America, and the eastern shores of Asia, is called the *Pacific* ocean; and that portion which separates Europe and Africa from America, the *Atlantic* ocean. Other portions are termed the *Northern*, *Southern*, and *Indian* oceans. When its waters penetrate into the land, they form what are called gulfs, and mediterranean seas. But without following it through all its windings and divisions, I shall simply state a few general facts.

With regard to the DEPTH of this body of water, no certain conclusions have yet been formed. Beyond a certain depth, it has hitherto been found unfathomable. We know, in general, that the depth of the sea increases gradually as we leave the shore; but we have reason to believe that this increase of depth continues only to a certain distance. The numerous islands scattered everywhere through the ocean, demonstrate, that the bottom of the waters, so far from uniformly sinking, sometimes rises into lofty mountains. It is highly probable, that the depth of the sea is somewhat in proportion to the elevation of the land; for there is some reason to conclude, that the present bed of the ocean formed the inhabited part of the ancient world, previous to the general Deluge, and that we are now occupying the bed of the former ocean; and if so, its greatest depth will not exceed four or five miles; for there is no mountain that rises higher above the level of the sea. But the sea has never been actually sounded to a greater depth than a mile and 66 feet Along the coast its depth has always been found proportioned to the hight of the shore; where the coast is high and mountainous, the sea that washes it is deep; but where the coast is low, the water is shallow. To calculate the *quantity of water* it contains, we must therefore suppose a medium depth. If we reckon its average depth at two miles, it will contain 296 millions of cubical miles of water. We shall have a more specific idea of this enormous mass of water, if we consider, that it is sufficient to cover the whole globe, to the hight of more than eight thousand feet; and if this water were reduced to one spherical mass, it would form a globe of more than 800 miles in diameter.

With regard to its BOTTOM—As the sea covers so great a portion of the globe, we should, no doubt, by exploring its interior recesses, discover a vast number of interesting objects. So far as the bed of the ocean has been explored, it is found to bear a great resemblance to the surface of the dry land; being, like it, full of plains, caverns, rocks, and mountains, some of which are abrupt and almost perpendicular, while others rise with a gentle acclivity, and sometimes tower above the water, and form islands. The materials, too, which compose the bottom of the sea are the same which form the bases of the dry land. It also resembles the land in another remarkable particular;—many fresh springs, and even rivers, rise out of it; an instance of which occurs near Goa, on the western coast of Hindostan, and in the Mediterranean sea, not far from Marseilles. The sea sometimes assumes *different colors*. The materials which compose its bottom cause it to reflect different hues in different places; and its appearance is also affected by the winds and by the sun, while the clouds that pass over it communicate all their varied and fleeting colors. When the sun shines, it is green; when he gleams through a fog, it is yellow; near the poles, it is black; while in the torrid zone, its color is often brown; and, on certain occasions, it assumes a luminous appearance, as if sparkling with fire.

---

* A more particular description of the phenomena of these terrific objects will be found in chap. iv, sect. 2.

The ocean has *three kinds of motions*. The first is that undulation which is produced by the wind, and which is entirely confined to its surface. It has been ascertained that this motion can be destroyed, and its surface rendered smooth, by throwing oil upon its waves. The second motion is that continual tendency which the whole water in the sea has toward the west, which is greater near the equator than toward the poles. It begins on the west side of America, where it is moderate; but as the waters advance westward, their motion is accelerated; and, after having traversed the globe, they return, and strike with great violence on the *eastern* shore of South America. Being stopped by that continent, they rush, with impetuosity, into the Gulf of Mexico, thence they proceed along the coast of North America, until they come to the south side of the great bank of Newfoundland, when they turn off and run down through the Western isles. This motion is most probably owing to the diurnal revolution of the earth on its axis, which is in a direction contrary to the motion of the sea. The third motion of the sea is the *tide*, which is a regular swell of the ocean every 12½ hours. This motion is now ascertained to be owing to the attractive influence of the moon, and also partly to that of the sun. There is always a flux and reflux at the same time, in two parts of the globe, and these are opposite to each other; so that when our Antipodes have high water, we have the same. When the attractive powers, of the sun and moon act in the same direction, which happens at the time of new and full moon, we have the highest, or *spring tides;* but when their attraction is opposed to each other, which happens at the quarters, we have the lowest, or *neap tides.*

Such is the ocean, a most stupendous scene of Omnipotence, which forms the most magnificent feature of the globe we inhabit. When we stand on the sea-shore, and cast our eyes over the expanse of its waters, until the sky and the waves seem to mingle, all that the eye can take in at *one* survey is but an inconsiderable *speck*, less than the hundred-thousandth part of the whole of this vast abyss. If every drop of water can be divided into 26 millions of distinct parts, as some philosophers have demonstrated,* what an immense assemblage of watery particles must be contained in the unfathomable caverns of the ocean! Here the powers of calculation are completely set at defiance; and an image of infinity, immensity, and endless duration, is presented to the mind. This mighty expanse of waters is the grand reservoir of Nature, and the source of evaporation, which enriches the earth with fertility and verdure. Every cloud which floats in the atmosphere, and every fountain, and rivulet, and flowing stream, are indebted to this inexhaustible source for those watery treasures which they distribute through every region of the land. In fine, whether we consider the ocean as rearing its tremendous billows in the midst of the tempest, or as stretched out into a smooth expanse—whether we consider its immeasurable extent, its mighty movements, or the innumerable beings which glide through its rolling waves—we cannot but be struck with astonishment at the grandeur of that Omnipotent Being who holds its waters in the "hollow of his hand," and who has said to its foaming surges, "Hitherto shalt thou come, and no farther; and here shall thy proud waves be stayed."

Rivers.—The next feature of the earth's surface which may be noticed, is the rivers with which it is indented in every direction. These are exceedingly numerous, and seem to form as essential a part in the constitution of our globe, as the mountains from which they flow, and as the ocean to which they direct their course. It is reckoned, that in the old continent, there are only about 430 rivers, which fall directly into the ocean, or into the Mediterranean and the Black seas; but in the new continent, there are only about 145 rivers known, which fall directly into the sea. In this enumeration, however, only the great rivers are included, such as the Thames, the Danube, the Wolga, and the Rhone. Beside these, there are many thousands of streams of smaller dimensions, which, rising from the mountains, wind in every direction, until they fall into the large rivers, or are carried into the ocean. The largest rivers in Europe are—the Wolga, which, rising in the northern parts of Russia, runs a course of 1700 miles, until it falls into the Caspian sea—the Danube, whose course is 1300 miles, from the mountains in Switzerland to the Black sea—and the Don, which runs a course of 1200 miles. The greatest rivers in Asia are—the Hoanho, in China, whose course is 2400 miles—the Boorhampooter, the Euphrates, and the Ganges. The longest river in Africa is the Nile, the course of which is estimated at 2000 miles. In the continent of America, the rivers appear to be formed on the grandest scale, both as to the length of their course, and the vast body of waters which they pour into the ocean. The Amazon, the largest river in the world, runs a course of above 3000 miles across the continent of South America, until it falls into the Atlantic ocean, where it discharges a body of waters 150 miles in breadth. Next to this is the river St. Lawrence, which is more than 2400 miles from its mouth through the lake of Ontario to the lake Alempigo and the Assiniboins; and the rivers La Plata and Mississippi, each of whose courses is not less than 2000 miles.

When we consider the number and the magnitude of these majestic streams, it is evident, that an enormous mass of water is continually pouring into the ocean from every direction. From observations which have been made on the river Po, which runs through Lombardy, and waters a tract of land 380 miles long and 120 broad, it is found, that it moves at the rate of four miles an hour, is 1000 feet broad and 10 feet in depth, and consequently, supplies the sea with 5068 millions of cubical feet of water in a day, or a cubical mile in 29 days. On the supposition that the quantity of water which the sea receives from the great rivers in all countries, is proportional to the extent and surface of these countries, it will follow, that the quantity of waters carried to the sea by all the other rivers on the globe, is 1083 times greater than that furnished by the Po (supposing the land, as formerly stated, to contain about 49 millions of square miles), and will supply the ocean with 13,630 cubical miles of water in a year. Now reckoning the ocean, as formerly, to contain 296 millions of cubical miles of water, this last number divided by the former, will give a quotient of 21,716. Hence it appears, that, were the ocean completely drained of its waters, it would require more than *twenty thousand years* * before its caverns could be again completely filled by all the rivers in the world running into it, at their present rate.

---

* The demonstration of this proposition may be seen in Nieuwentyt's Religious Philosopher, vol. iii, p. 852.

Here two questions will naturally occur—Whence do the rivers receive so constant a supply of water? and, Why has not the ocean long ago overflowed the world, since so prodigious a mass of water is continually flowing into its abyss? This was a difficulty which long puzzled philosophers; but it is now satisfactorily solved, from a consideration of the effects of evaporation. By the heat of the sun, the particles of water are drawn up into the atmosphere, from the surface of the ocean, and float in the air in the form of clouds, or vapor. These vapors are carried, by the winds, over the surface of the land, and are again condensed into water on the tops and the sides of the mountains, which, gliding down into their crevices and caverns, at length break out into springs, a number of which meeting in one common valley, become a river; and many of these united together, at length form such streams as the Tay, the Thames, the Danube, and the Rhine. That evaporation is sufficient to account for this effect, has been demonstrated by many experiments and calculations. It is found, that from the surface of the Mediterranean sea, which contains 762,000 square miles, there are drawn up into the air every day, by evaporation, 5280 millions of tons of water, while the rivers which flow into it yield only 1827 millions of tons in the same time; so that there is raised in vapor from the Mediterranean nearly *three times* the quantity of water which is poured into it by all its rivers. One third of this falls into the sea before it reaches the land; another part falls on the low lands, for the nourishment of plants; and the other third part is quite sufficient to supply the sources of all the rivers which run into the sea. This is in full conformity to what was long ago stated by an inspired Naturalist; "All the rivers run into the sea, and yet the sea is not full; unto the place from whence the rivers came, thither do they return again;" but, before they regain their former place they make a circuit over our heads through the regions of the atmosphere.

Such are the varied movements and transformations which are incessantly going on in the rivers, the ocean, and the atmosphere, in order to preserve the balance of nature, and to supply the necessities of the animal and vegetable tribes; all under the agency and direction of Him who "formed the sea and the dry land," and who has arranged all things in number, weight, and measure, to subserve the purposes of his will.

Rivers serve many important purposes in the economy of our globe. They carry off the redundant waters which fall in rains, or which ooze from the springs, which might otherwise settle into stagnant pools; they supply to the seas the loss of waters occasioned by their daily evaporation; they cool the air, and give it a gentle circulation; they fertilize the countries through which they flow; their waters afford a wholesome drink, and the fishes they contain a delicious food for the nourishment of man; they facilitate commerce, by conveying the productions of nature and art from the inland countries to the sea; they form mechanical powers for driving machinery of different kinds; they enliven and diversify the scenery of the countries through which they pass; and the cataracts which they frequently form among the mountains, present us with scenes the most picturesque and sublime; so that every part of the constitution of nature is rendered subservient both to utility and to pleasure.

Waving the consideration of other particulars, I shall simply state some of the artificial divisions of the earth, and two or three facts respecting its inhabitants.

The LAND has generally been divided into four parts, Europe, Asia, Africa, and America, to which has been lately added the division called Australasia, which comprehends, New Holland, New Guinea, New Zealand, Van Dieman's Land, and several other islands in the Pacific ocean.

Europe comprehends the following countries—Norway, Sweden, Denmark, Russia, Prussia, Germany, Austria, Turkey, Italy, Switzerland, France, Holland, Belgium, or the Netherlands, Spain, Portugal, and Great Britain and Ireland, together with the islands of Sicily, Malta, Candia, Corsica, Sardinia, Majorca, Minorca, Ivica, Zealand, Funen, Gothland, Iceland, and several others of smaller note.

Europe is the smallest of the five grand divisions of the globe. Its greatest extent is from northeast to southwest, namely, from the mouth of the Kara in N. Lat. 68° 40″ to the rock of Lisbon in N. Lat. 38° 45″, which is computed at 3400 British miles. Its greatest breadth, from Cape Matapan, in the Morea, to the North Cape of Norway, is computed at 2350 miles. Its superficial contents have been computed at 3,650,000 square miles, or 2,336,000,000 English acres, reckoning 640 to the square mile. Its form is singularly broken and varied, being split into many distinct portions, peninsulas, and large islands with extended and winding coasts, which arises chiefly from the number of its inland seas, of which the Mediterranean, the Baltic, and the Black sea, are the most important. Its *rivers* are numerous, the largest of which are the Rhine, the Rhone, the Wolga, and the Danube. Its *mountains* do not reach that stupendous hight, nor extend in such unbroken chains, as those of Asia and America. Its highest ranges are the Alps and Pyrenees, the Appennines in Italy, and the Dofrafield, in Norway. Its *lakes*, though numerous, are comparatively small; those of Ladoga and Onega alone being of any commercial importance. Its *soil* is distinguished for its valuable productions: Grain of different kinds is raised over its whole surface, except in the extreme north—wines throughout all its southern region; and it is equally productive in hemp, flax, wool, and silk. Its northern forests produce some of the finest timber in the world; and the iron of Europe surpasses that of any other country. The cultivation of the soil is carried on with great diligence, and in point of science, skill, and the extent of capital employed upon it, and upon every branch of commerce and manufacture, it stands unrivaled among the other countries of the globe. Its commerce is on a very extensive scale, and in manufacturing skill it has surpassed every other country, both in the variety and the cheapness of its productions. European vessels, conveying articles and manufactures of all descriptions, are to be found at the utmost bounds of Asia and America, in the snowy regions of the poles, and crowding the ports of New Holland, Van Dieman's Land, New Zealand, and the islands of the Indian and Pacific oceans.

---

* Buffon makes this result to be 812 years, in which he is followed by Goldsmith, and more subsequent writers; but he proceeds on the false assumption, that the ocean covers only half the surface of the globe, and that it contains only 85 millions of square miles, and he estimates the average depth of the ocean to be only 140 yards, or one-fourth of a mile.

The *population* of Europe is now reckoned to amount to about 200 millions. Its inhabitants are divided chiefly into three races, the Sclavonic, Teutonic, and Romish races. The *Sclavonic* consists of about 25 millions of Russians, 10 millions of Poles, and 10 millions in other adjacent countries. The *Teutonic* race, which occupy the greater part of Scandinavia, the Netherlands, and Great Britain, may be estimated at 50 millions. The *Romish* race includes the inhabitants of Southern Europe, France, Italy, Spain, etc., and may be estimated at about 80 millions. The Celts in Scotland, Ireland, Wales, and Spain, are the remains of the most ancient inhabitants of Western Europe, and may amount to 6 millions. The Greeks in Europe amount to 2 millions, and the Jews throughout all Europe to about 2 millions. The Tartars, Turks, Hungarians, and Gypsies, which are of Asiatic origin, amount altogether to 6 or 7 millions. Though this division of the earth is least in point of size—being only the one sixteenth part of the terraqueous globe—it is yet by far the greatest as to moral, political, and commercial importance. Its surface is in general more crowded with inhabitants than most other countries (China excepted), more improved by cultivation, more enriched by industry and commerce—embellished with mighty cities, and splendid works of art, and illuminated with the reflections of genius. Here we behold mind asserting its supremacy over matter, and man, the lord of this lower world, pursuing the high destiny originally assigned him "to replenish the earth and subdue it." In learning, arts, and sciences, Europe has far surpassed every other portion of the globe; and by the invention of Printing, knowledge of every description is now rapidly diffused, and promoting the moral and intellectual improvement of its population.

Asia, the largest and most populous division of the ancient continent, contains the empires of China and Japan, Chinese Tartary, Thibet, Hindostan, or British India, the Birman Empire, Persia, Arabia, Turkey in Asia, Siberia, Independent Tartary, and a variety of territories inhabited by tribes with which we are very imperfectly acquainted; together with the immense islands of Borneo, Sumatra, Java, Ceylon, Segalien, the Philippines, and thousands of others of smaller dimensions. The immense expanse of Asia presents every possible variety of soil and climate, as it extends from the confines of the polar regions to the tropical climes. Its grandest feature is a chain of mountains crossing it from the Mediterranean to the Eastern seas, of which Taurus, Caucasus, and the Himalaya are the portions best known. One leading feature of middle Asia consists in large lakes or inland seas, salt like the ocean, and having no outlets; of which the Caspian, the Sea of Aral, and Baikal, are the largest. It contains many rivers of great magnitude. The Euphrates, the Ganges, the Hoanho, and the Amur, in the length of their course, yield only to the rivers of the New world. This quarter of the globe is reckoned to be 7500 miles in length, from east to west, and about 5000 miles in breadth, from south to north, and contains about 16 millions of square miles, being more than four times larger than Europe. Its inhabitants have been computed by some writers to amount to 580 millions. It was in Asia where the human race was first planted; it became the nursery of the world after the universal deluge, and it was the scene in which the most memorable transactions recorded in the sacred history took place. But its inhabitants are now immersed in Mahometan and Pagan darkness; and the Christian Religion, except in a few insulated spots, is almost unknown among its vast population. It is the richest and most fruitful part of the world, and produces cotton, silks, spices, tea, coffee, gold, silver, pearls, diamonds, and precious stones: but despotism, in its worst forms, reigns, uncontrolled over every part of this immense region.

Africa comprehends the following kingdoms—Morocco, Algiers, Tunis, Tripoli, Egypt, Zaara, Negroland, Guinea, Nubia, Abyssinia, Caffraria, Dahomey, Benin, Congo, Angola, and various other territories. By far the greater part of Africa remains hitherto unexplored, and, consequently, we are possessed of a very slender portion of information respecting the numerous tribes that may inhabit it. This quarter of the world, which once contained several flourishing kingdoms and states, is now reduced to a general state of barbarism. That most abominable traffic, the slave trade, is carried on to an unlimited extent on its western coasts, by a set of European ruffians, whose villanies are a disgrace to human nature. It is to be hoped, this traffic will, ere long, be extirpated by the efforts now making by European nations, and by the plans which are now concerting for promoting the religious, moral, and commercial improvement of this country. The Christian Religion has lately been introduced into its southern regions, in the districts adjacent to the Cape of Good Hope, and the labors of Missionaries of different denominations appear, in numerous instances, to have been crowned with remarkable success.*—A colony of blacks, formerly slaves in America, has lately been established on the western coast, a little to the south of Sierra Leone, which goes by the name of *Liberia*. All the affairs of this little state are conducted by emancipated negroes, and particular attention is paid to the literary and religious instruction of the colonists. Some of the Newspapers we have seen, published by the settlers in this colony, indicate a considerable degree of talent and information; and there is a prospect that the improvements going forward in Liberia will, ere long, produce a beneficial influence on those tribes who occupy the adjacent territories, and have a tendency to lessen the traffic in slaves The greatest breadth of Africa is about 4790 miles, and its length from north to south about 5000 miles. Its most striking features are those immense deserts, near its northern parts, which comprise nearly one-third of its surface. The deserts of Zaara are 1500 miles long and eight hundred broad.

America is divided into North and South. It remained unknown to the inhabitants of the Eastern hemisphere until the year 1492, when it was discovered by Columbus, who first landed on Guanahani, or *Cat Island*, one of the Bahama isles. North America comprehends the following countries: The United States, New and Old Mexico, Upper and Lower Canada, Nova Scotia, New Brunswick, and Labrador. South America comprehends the immense districts called Terra Firma, Peru, Guiana, Amazonia, Paraguay, Brazil, Chili, and Patagonia.—Between N. and S. America, lie the islands of Cuba, St. Domingo, Jamaica, and Porto Rico, known by the name of the *West Indies*. America is bounded on the east by the Atlantic, on the west by the Pacific, and on the north by the Arctic ocean. South America comprises a surface of six and a half millions of square miles, its length being 4500 miles, and its greatest breadth 3200 miles. North America, exclusive of the islands that surround it, contains about nine millions of square miles. It has been divided into five physical regions: 1. The table land of Mexico; 2. The slope lying between the rocky mountains and the Pacific ocean; 3. The great valley of the Mississippi; 4. The eastern declivity of the Alleghany mountains; 5. The great northern plain beyond 50° north latitude, a bleak and barren waste, covered with lakes. Beside these, there are connected with America, the Bahama and Caribbee islands, Newfoundland, Cape Breton, Tobago, Trinidad, Terra del Fuego, etc. America is distinguished by its numerous and extensive lakes, which resemble large inland seas. Its rivers, also, form one of its grand and distinguishing features, being the largest on the globe. It is likewise diversified with lofty and extensive ranges of mountains. When first discovered, it was almost wholly covered with immense forests and thinly peopled with a number of savage tribes. Its mingled population of Aborigines and Europeans is now making rapid advances in knowledge, civilization, and commerce.

---

* See Moffat's interesting work, entitled "Missionary Scenes and Labors in Southern Africa." 1842.

The *United States*, which extend from the 20th to the 50th degree of north latitude, form the greatest and most influential power that exists on this continent, and possess a territory of vast extent—stretching from the great lakes to the Gulf of Mexico, a breadth of about 1600 miles; and from the Atlantic to the Pacific ocean, a length of 2500 miles, including a surface of 2,300,000 square miles. The population of these States now amounts to about 15 millions—an astonishing number, when we consider that only a little more than 200 years ago these territories were little else than a boundless wilderness, peopled by a few tribes of savages. Were they brought to a cultivated state, they would be sufficient to subsist a population of three or four hundred millions. These States have been peopled from different European nations, particularly from Great Britain and Ireland, and the English language prevails over most of the 26 States. The form of government is that of a republic; and in religion they have adopted the system of cutting off all connection between church and state. Every sectary chooses its own pastor and provides entirely for his support. Literature and science have not yet reached the high elevation they have attained in Europe; but numerous colleges, highly respectable, and literary institutions of various descriptions, have been established,—some of which enjoy a high reputation. The education of the mass of the community forms a prominent object of attention in each state; and the benefits of a good common education are perhaps more generally diffused than in any other country in the world. It is much to be regretted that the system of slavery still prevails in the *Southern* states, notwithstanding all the remonstrances which have been made against it by the inhabitants of the Northern states, and by other nations. But it is to be hoped that the good sense of the inhabitants of these states will, ere long, excite them to arouse themselves to remove that blot upon their national character by which their institutions have been so long and so deeply disgraced.

Australasia is the name given to a number of large islands occupying a portion of the Indian or Southern Pacific ocean, between the 10th and 45th degrees of south latitude. The chief island in the group is New Holland or *Australia*, the largest island in the world, being about 2400 miles in length, from east to west, and 1800 from north to south, comprising an area of nearly three millions of square miles. The country is generally flat, with the exception of some mountain-ranges, and in many places the *inclination* is inward, instead of outward toward the sea, so that the mountains and elevated land form a ridge nearly round it. The great Kangaroo is the largest quadruped in this country, and the total absence of such animals as lions, tigers, deer, oxen, horses, bears, is the most striking feature in this region. The native human beings are of the Malay race, and exist in the lowest state of degradation and barbarism.—Three British settlements have been formed in New Holland: 1. *New South Wales*, which stretches about 1400 miles along its eastern coast, and some hundreds of miles inland.—This is the oldest and most populous of the Australian colonies, and was selected at first for the transportation of convicts, though voluntary emigrants, of late years, have emigrated thither in considerable numbers. It lies at the distance of about 16,000 miles from Great Britain; but the voyage to it is generally accomplished in from 100 to 120 days. Its capital, *Sydney*, pleasantly situated on a fine bay, called Port Jackson, is now considered as containing a population of 25,000. The whole population of this colony, free and convict, is calculated to be about 110,000, and it is rapidly increasing. 2. Western Australia, or the *Swan-river settlement*, which is not so populous, nor does it appear so prosperous as the other settlements. 3. *South Australia*—which lies on the southern shore. In this colony slavery is not permitted to exist, nor are any convicts allowed to be sent to it from England. Here learning and religion are greatly encouraged, and every mean has been employed by the directors of the South Australian Company to render the settlers, as far as possible, a moral and religious population. The capital is *Adelaide*, which already contains about 7000 inhabitants, although it is only about five years since the colony was established. Each denomination of Christians supports its own ministers and places of worship; and already about £15,000 have been expended in Adelaide and its vicinity in erecting chapels for Christian worship. Three millions of capital have been invested in this province up to the 1st December, 1841, and 491,984 acres of land have been surveyed. The climate is one of the finest and most salubrious in the world, and it has sometimes been alluded to as "the fair and fertile province of South Australia." Its winter, which is mild, is in May, June, and July; and its summer in November, December, and January.

Van Dieman's Land is an island of about the size of England, which is separated from New Holland by a channel 90 miles wide, called Bass's Strait. Its shape is nearly that of a parallelogram. It is more hilly and better watered than Australia, and possesses many excellent harbors. Its capital is Hobart-Town, situated on the southern side of the island, and on the northern shore is Launcetown, the second town, and a busy seat of trade. The population of the island was lately estimated at 25,000, of which about one half were convicts.

New Zealand consists chiefly of two large islands, called the Middle Island, and the North Island, separated by a passage called Cook's Straits, with numerous smaller isles scattered around their shores. They lie in an easterly direction from New Holland, at a distance of about 1200 miles from that continent, between the 34th and 48th degrees of south latitude, and the 166th and 179th of east longitude. The southern island is about 500 miles long, and nearly 120 broad. The northern is about 400 miles long, and from 5 to 30 broad. Both the islands are estimated to contain 95,000 square miles, of which two-thirds are fit for cultivation. Numbers of fine streams and rivers are scattered through the country, and the bays and harbors are not surpassed either in number or advantages by those of any country in the world. A chain of mountains runs through the whole of the southern and a considerable part of the northern island, some of the tops of which are as high as 14,000 feet above the level of the sea, and present a highly picturesque appearance. All accounts agree that the climate is highly salubrious, and very congenial to European constitutions. The natives of this country were formerly savage and dangerous, but are now partially improved and comparatively harmless in disposition, the missionaries having now acquired a considerable influence over certain tribes. It is universally admitted that they are a robust and healthy looking people; and Captain Cook observes that he never saw a single person among them who appeared to have any bodily complaint, and that their wounds healed with astonishing rapidity. The entire population of this country has been estimated at 158,000, which is at the rate of 5 persons to 3 square miles. The *New Zealand Company* for colonizing this country was established in May, 1839, and is now employed in carrying its plans into effect. Land has been purchased from the natives, and a considerable number of adventurers have already taken possession of certain districts. A township has been marked out on the shores of Port Nicholson—a fine harbor in the Northern Island about the center of Cook's straits—to be named Wellington, which it is supposed will be the capital of the colony. But apprehensions are entertained that misunderstandings and serious disputes may arise between the settlers and the natives, and that the runaway convicts from Botany Bay, and the southern whalers, will introduce dissension and immorality among the colonists.

New Guinea, next to New Holland, is the largest island of Australasia, being 1400 miles long. It is inhabited by Papuans, with the still ruder race of Haraforas in the interior. This island is said to be one of the finest countries in existence, producing most of the rich fruits of the torrid zone, such as cocoas, nutmegs, cloves, and spices of all kinds, and is everywhere covered with lofty forests. The Papuans are much farther advanced in civilization than the New Hollanders; but no European nation has yet attempted a settlement in this island.—*New Britain*, *New Ireland*, and several others, compose a group inhabited by Papuans. The Archipelago, called the *Solomon's islands*, is inhabited by Papuans, with a mixture of Malays.

Polynesia, or "the many isles," includes the numerous group of islands with which a considerable portion of the Pacific ocean is diversified. They principally lie in an easterly and north-easterly direction from Australasia, within about 30 degrees on both sides of the equator. They are many thousands in number, and are inhabited by savage races, who have generally been found more tractable than the barbarous tribes of other parts of the world. They may be divided into the great groups of the *Society*, *Sandwich*, *Marquesas*, *Friendly*, *Navigators*, *Caroline*, and *Marianne islands*, with several others. Most of these islands are fruitful and beautiful; some are exceedingly high and romantic, and their climate is reckoned the most delicious on the globe. The *Society* islands, though not the largest, are the most beautiful, and those in which civilization and polished manners have made the greatest progress. Tahiti, the largest in the group, is one of the brightest gems of the Pacific, as the people of this island were the first to abjure Paganism and to embrace Christianity. It consists of two peninsulas, joined by a narrow isthmus. The one is about 25 miles long and about the same in breadth. The other is about 20 miles in length by 15 in breadth. The religion of the natives, like that of the Tonga, Sandwich, and other islanders, was, until within these 20 or 30 years, idolatry of the most barbarous kind, their manners were extremely licentious, and their dispositions sometimes ferocious and cruel. They were perpetually at war among themselves, and their contests were of the most relentless and cruel character. But, in consequence of the labors of Christian Missionaries, sent out by the London Missionary Society, the majority of the inhabitants of this and the adjacent islands have made an open profession of Christianity. Their places of idolatrous worship have been thrown down, their idol gods destroyed, and an end put to their ferocious and destructive wars. The whole of the Sacred Scriptures has been translated into their native language; they are learning to read the word of God; and, in numerous instances, they have made a wonderful progress in studying its facts and doctrines, and in practicing those duties which it enjoins. The consequence has been that they have made a great improvement in all the arts and accommodations of life. They have built ships, engaged in manufactures of different kinds, reared spacious places of worship, established schools and other seminaries of instruction, erected villages adorned with neat and commodious habitations, and have made astonishing progress in the cultivation of the soil. The moral transformation and improvements which have been effected among the inhabitants of these islands in consequence of the introduction of Christianity—afford a striking and incontestable proof, that there are no tribes on the face of the earth, however barbarous and debased, but may be raised to the dignity of their moral and intellectual natures, were the religion of the Bible once introduced among them, and every other judicious mean employed to promote their progress in knowledge and civilization.

The *Sandwich Islands* lie about 20 degrees north of the equator, and about 2500 miles north by west of Tahiti. *Owhyhee*, the largest of the group, is remarkable for the murder of the celebrated Capt. Cook in 1779. It measures 84 miles in length, by 70 in breadth. It abounds with lofty mountains. Mount Roa rises to the hight of 16,000 feet, and Mount Koa to the hight of 13,000 feet, the tops of both being covered with perpetual snow. It also abounds with volcanoes. The volcano of Peli, on the flank of Mount Roa, is reckoned one of the most striking and awful in any part of the world. The people of the Sandwich islands have, of late years, embraced Christianity, and several missionaries from the United States are now settled in those regions. A considerable part of the population, including the king and his court, attend the schools they have established, and the ordinances of Christian worship. They have formed a small navy, and carry on a profitable trade with foreigners, and the general state of morals is undergoing a great improvement.

The *Friendly Islands* include the Fejee, and several other detached islands, of which Tongataboo is the largest. They enjoy a remarkably rich soil, which is carefully cultivated by the natives, who rank among the most respectable of the South-Sea islanders, and are remarkable for their neatness and skill in improving and inclosing their lands. Christianity has been lately introduced into some of these islands, chiefly by the persevering labors of the Wesleyan Missionaries. Their population is reckoned at about 100,000.—The *Navigators' Islands* are among the most important and fertile group yet discovered in Southern Polynesia. The natives are uncommonly tall and stout, and remarkable for a ferocity of character scarcely found in any other part of *Polynesia*. Here, however, the Christian religion has lately been introduced, and is already producing many interesting and beneficent effects. — The *Marquesas* are situated north by east from the Society isles, within 9° of the Equator. Their inhabitants are distinguished for their fair complexion and peculiar beauty, but they are fierce and licentious in their character. Christianity has been introduced, but has hitherto produced little effect upon them.—The *New Hebrides* are a group generally covered with high mountains, some of which contain volcanoes. They are situated about five or six hundred miles west of the Friendly isles, and were first discovered by Quiros in 1606, when they were supposed to be part of a great southern continent which philosophers then imagined to exist. But Cook, in 1774, explored the whole group, and gave them the name of the New Hebrides. The cluster consists of about 17 islands, of which *Terra del Espiritu Santo* is the largest. At *Erromango*, one of these islands, the deeply-lamented missionary WILLIAMS was treacherously and cruelly murdered by the natives, along with another missionary of the name of HARRIS, in 1839, when attempting to introduce Christianity among them. This island will be as much distinguished in future ages for this atrocious murder as the island of Owhyhee has been for the murder of Captain Cook. The geographical discoveries of this celebrated circumnavigator prepared the way for most of the missionary operations which have been undertaken in the islands of the Pacific, and of all the laborers in this work of philanthropy, none stands so conspicuous, for unwearied beneficent exertions in this holy cause, and for the important and beneficial effects with which they have been accompanied as the lamented WILLIAMS. His "Narrative of Missionary Enterprises in the South-Sea Islands," deserves to be read by every Christian, by every philosopher and statesman, and by every one who feels a delight in contemplating beneficent actions and romantic incidents.

In regard to the *human inhabitants* that occupy the different regions now specified—they have been divided by some geographers into the six following classes:—1. The dwarfish inhabitants of the polar regions; as the Laplanders, the Greenlanders, and the Esquimaux. 2. The flat-nosed olive-colored tawny race; as the Tartars, the Chinese, and the Japanese. 3. The blacks of Asia with European features. Of this description are the Hindoos, the Birmans, and the inhabitants of the islands of the Indian ocean. 4. The woolly-haired negroes of Africa, distinguished by their *black* color, their flat noses, and their thick lips. 5. The copper-colored native Americans, distinguished likewise by their black hair, small black eyes, high cheek bones, and flat noses. 6. The sixth variety is the white European nations, as the British, the French, the Italians, and the Germans.

The *number of inhabitants* which people the earth at one time, may be estimated to amount to at least *eight hundred millions;* of which 500 millions may be assigned to Asia; 58 millions to Africa; 42 millions to America; and 200 millions to Europe.—With regard to their religion, they may be estimated as follows:—

Pagans,	490,000,000
Mahometans,	100,000,000
Roman Catholics,	100,000,000
Protestants,	55,000,000
Greeks and Arminians,	50,000,000
Jews,	5,000,000
	800,000,000

From this estimate it appears that there are nearly 3 Pagans and Mahometans to 1 Christian, and only 1 Protestant to about 14 of all the other denominations. Although all the Roman Catholics, Greeks, and Protestants, were reckoned true Christians, there still remain more than 595 millions of our fellow-men ignorant of the true God, and of his will as revealed in the sacred Scriptures; which shows that a vast field of exertion still lies open to Christian benevolence, before the blessings of civilization, mental improvement, rational liberty, and Christianity, be fully communicated to the Pagan and Mahometan world.

If we suppose that the earth, at an average, has always been as populous as it is now, and that it contains 800 millions of inhabitants, as above stated, and if we reckon 32 years for a generation, at the end of which period the whole human race is renewed; it will follow, that one hundred and forty-six thousand two hundred millions of human beings have existed on the earth since the present system of our globe commenced, reckoning 5846 years from Adam to the present time.* And consequently, if mankind had never died, there would have been nearly 183 times the present number of the earth's inhabitants now in existence. It follows from this statement, that 25 millions of mankind die every year, 2853 every hour, and 47 every minute, and that at least an equal number, during these periods, are emerging from non-existence to the stage of life; so that almost every moment a rational and immortal being is ushered into the world, and another is transported to the invisible state. Whether, therefore, we contemplate the world of matter, or the world of mind, we perceive incessant changes and revolutions going on, which are gradually carrying forward the earth and its inhabitants to some important consummation.—If we suppose that before the close of time, as many human beings will be brought into existence, as have already existed during the bypast ages of the world, there will, of course, be found at the general resurrection 292,400,000,000 of mankind. Vast as such an assemblage would be, the whole of the human beings here supposed, allowing six square feet for every individual, could be assembled within the space of about 62,400 square miles, or on a tract of land not much larger than that of England, which contains, according to the most accurate calculation, above 50,000 square miles.

---

* This calculation proceeds on the supposition, that only 4004 years elapsed between the creation of man and the birth of Christ, according to the Hebrew Chronology. But Dr. Hales, in his late work on Scripture Chronology, has proved almost to a demonstration, that from the Creation to the birth of Christ, are to be reckoned 5411 years; and this computation nearly agrees with the Samaritan and Septuagint Chronology, and with that of Josephus. According to this computation, 7253 years are to be reckoned from the Creation to the present time; and consequently, 220 thousand 500 millions of human beings will have existed since the Creation, which is more than 226 times the number of inhabitants presently existing.

Our world is capable of sustaining a much greater number of inhabitants than has ever yet existed upon it at any one time. And since we are informed in the Sacred oracles that God "created it not in vain, but *formed it to be inhabited*," we have reason to believe that, in future ages, when the physical and moral energies of mankind shall be fully exerted, and when peace shall wave her olive-branch over the nations, the earth will be much more populous than it has ever been, and those immense deserts, where ravenous animals now roam undisturbed, will be transformed into scenes of fertility and beauty. If it be admitted that the produce of twelve acres of land is sufficient to maintain a family consisting of six persons, and if we reckon only one-fourth of the surface of the globe capable of cultivation, it can be proved that the earth could afford sustenance for 16,000 millions of inhabitants, or *twenty times the number* that is presently supposed to exist.—So that we have no reason to fear that the world will be overstocked with inhabitants for many ages to come; or that a period may soon arrive when the increase of population will surpass the means of subsistence, as some of the disciples of Malthus have lately insinuated. To suppose, as some of these gentlemen seem to do, that wars and diseases, poverty and pestilence, are necessary evils, in order to prevent the increase of the human race beyond the means of subsistence which nature can afford—while the immense regions of New Holland, New Guinea, Borneo, and the greater part of Africa and America are almost destitute of inhabitants—is both an insult on the dignity of human nature and a reflection on the wisdom and beneficence of Divine Providence.—The Creator is benevolent and bountiful, and "his tender mercies are over all his works;" but man, by his tyranny, ambition, and selfishness, has counteracted the streams of Divine beneficence, and introduced into the social state poverty, disorder, and misery, with all their attendant train of evils; and it is not before such demoralizing principles be in some measure eradicated, and the principles of Christian benevolence brought into active operation, that the social state of man will be greatly meliorated, and the bounties of Heaven fully enjoyed by the human race. If, in the present deranged state of the social and political world, it be found difficult in any particular country to find sustenance for its inhabitants, emigration is the obvious and natural remedy; and the rapid emigrations which are now taking place to the Cape of Good Hope, New Holland, New Zealand, Van Dieman's Land, and America, are doubtless a part of those arrangements of Providence, by which the Creator will accomplish his designs, in peopling the desolate wastes of our globe, and promoting the progress of knowledge and of the true religion among the scattered tribes of mankind.

With that branch of knowledge to which I have now adverted, every individual of the human race ought to be in some measure acquainted.—For it is unworthy of the dignity of a rational being, to stalk abroad on the surface of the earth, and enjoy the bounty of his Creator, without considering the nature and extent of this sublunary habitation, the variety of august objects it contains, the relation in which he stands to other tribes of intelligent agents, and the wonderful machinery which is in constant operation for supplying his wants, and for producing the revolutions of day and night, spring and autumn, summer and winter.—In a religious point of view. Geography is a science of peculiar interest. For "the salvation of God," which Christianity unfolds, is destined to be proclaimed in every land, in order that men of all nations and kindreds and tongues may participate in its blessings. But, without exploring every region of the earth, and the numerous islands which are scattered over the surface of the ocean, and opening up a regular intercourse with the different tribes of human beings which dwell upon its surface, we can never carry into effect the purpose of God by "making known his salvation to the ends of the earth."—As God has ordained, that "all flesh shall see the salvation" he has accomplished, and that human beings shall be the agents for carrying his designs into effect—so we may rest assured, that he has ordained every mean requisite for accomplishing this end; and consequently, that it is his will that men should study the figure and magnitude of the earth, and all those arts by which they may be enabled to traverse and explore the different regions of land and water, which compose the terraqueous globe—and that it is also his will, that every one who feels an interest in the present and eternal happiness of his fellow-men, should make himself acquainted with the result of all the discoveries in this science that have been or may yet be made, in order to stimulate his activity, in conveying to the wretched sons of Adam, wherever they may be found, "the unsearchable riches of Christ."

To the Missionary, and the Directors of Bible and Missionary Societies, a minute and comprehensive knowledge of this science, and of all the facts connected with it, is essentially requisite without which they would often grope in the dark, and spend their money in vain, and "their labor for that which doth not profit." They must be intimately acquainted with the extensive field of operation which lies before them, and with the physical, the moral, and the political state of the different tribes to which they intend to send the message of salvation; otherwise their exertions will be made at random, and their schemes be conducted without judgment or discrimination. To attempt to direct the movements of Missionary Societies, without an intimate knowledge of this subject, is as foolish and absurd as it would be for a land-surveyor to lay down plans for the improvement of a gentleman's estate, before he had surveyed the premises, and made himself acquainted with the objects upon them, in their various aspects, positions, and bearings. If all those who direct and support the operations of such societies were familiarly acquainted with the different fields for missionary exertions, and with the peculiar state and character of the diversified tribes of the heathen world, so far as they are known, injudicious schemes might be frustrated before they are carried into effect, and the funds of such institutions preserved from being wasted to no purpose. In this view, it is the duty of every Christian, to mark the progress and the results of the various geographical expeditions which are now going forward in quest of discoveries, in connection with the moral and political movements which are presently agitating the nations: for every navigator who plows the ocean in search of new islands and continents, and every traveler who explores the interior of unknown countries, should be considered as so many pioneers, sent beforehand, by Divine Providence, to prepare the way for the labors of the missionary, and for the combined exertions of Christian benevolence.*

But even to every private Christian, Geography is an interesting branch of study, without some knowledge of which, his prayers and his Christian sympathies cannot be judiciously and extensively directed. We occasionally hear the ministers of religion, at the commencement of public worship on the first day of the week, imploring the Divine blessing on their brethren throughout the Christian Church, who are commencing the same exercises; and at the close of worship in the afternoon, that the same blessing may seal the instructions which have been delivered in all the churches of the saints; as if all the public religious services of the universal Church were at that moment drawing to a close. This is all very well, so far as it goes: the expression of such benevolent wishes is highly becoming, and congenial to the spirit of Christianity. But a very slight acquaintance with geographical science will teach us, that when we in this country are commencing religious services of the first day of the week, our Christian brethren in the East Indies, who live under a very different meridian, have finished theirs; those in Russia, Poland, Greece, Palestine, and on the banks of the Caspian sea, have performed one-half of their public religious worship and instructions; and those in New Holland and Van Dieman's Land have retired to rest at the close of their Sabbath. On the other hand, our friends in the West India islands, and in America, at the close of our worship, are only about to commence the public instructions of the Christian Sabbath. If, then, it be admitted that our prayers, in certain cases, ought to be *specific*, to have a reference to the particular cases and relations of certain classes of individuals, there can be no valid reason assigned, why they should not have a reference to the geographical positions of the different portions of the Christian Church, as well as to those who live on or near our own meridian: that, for example, in the beginning of our public devotions, we might implore that the blessing of God may accompany the instructions which have been delivered in the Eastern parts of the world; and that at the close of the worship, that the same agency may direct the exercises of those in the Western hemisphere, who are about to enter on the sacred services of that day. On the same principle we may perceive the absurdity of those "*concerts*" for praying in different places *at the same hour*, which were lately proposed, and attempted by a certain portion of the religious world. Even within the limits of Europe, this could not be attempted, with the prospect of Christians joining in devotion at one and the same time; for when it is six o'clock in one part of Europe, it is eight in another, and five o'clock at a third place; much less could such a concert take place throughout Europe, Asia, and America. So that science, and a calm consideration of the nature and relations of things, may teach us to preserve our devotional fervor and zeal within the bounds of reason and propriety; and, at the same time, to direct our reflections and our Christian sympathies, to take a wider range than that to which they are usually confined.

Beside the consideration now suggested, a serious contemplation of the physical objects and movements which this science exhibits, has a tendency to excite pious and reverential emotions. To contemplate this huge globe of land and water, flying with rapidity through the voids of space, conveying its vast population from one region to another, at the rate of fifteen hundred thousand miles in a day, and whirling round its axis at the same time, to produce the constant succession of day and night,—to contemplate the lofty ridges of mountains that stretch around it in every direction; the flaming volcanoes; the roaring cataracts; the numerous rivers, incessantly rolling their watery treasures into the seas; the majestic ocean, and its unfathomable caverns; the vapors rising from its surface, and replenishing the springs and rivers; the avalanche hurling down the mountain's side with a noise like thunder; the luxuriant plains of the torrid zone; the rugged cliffs and icebergs of the polar regions; and thousands of other objects of diversified beauty and sublimity,—has an evident tendency to expand the conceptions of the human mind, to increase its sources of rational enjoyment, and to elevate the affections to that All-powerful Being who gave birth to all the sublimities of Nature, and who incessantly superintends all its movements.

---

* On this subject the Author feels great pleasure in referring his readers to a small volume, lately published by James Douglas, Esq., of Cavers, entitled, "Hints on Missions,"—a work which deserves the attentive perusal, both of the philosopher, the politician, and the Christian, and particularly of the Directors of Missionary Societies; and which is characterized by a spirit of enlightened philanthropy, and *a condensation of thought*, which has seldom been equaled in the discussion of such topics. It concentrates, as it were, into a focus, the light of which has been reflected from hundreds of volumes; and the original hints it suggests claim the serious consideration of the superintendents of missionary schemes; without an attention to some of which, the beneficial effects resulting from such undertakings will be few and unimportant.—The following excellent works, recently published on this subject, are warmly recommended to the serious attention of the reader:—1. "*The Great Commission*," by Dr. Harris, President of Cheshunt College, Author of "Mammon," etc.—a prize Essay on Christian Missions, to which the highest prize of 200 guineas was awarded. This work has been generally characterized as "A masterly production, comprehensive in plan, elegant in diction, happy in illustration, cogent and conclusive in reasoning, powerful in appeal, and a book which every Christian in the world ought to read." 2. "*Missions*, their authority, scope, and encouragement," by the Rev. Richard W. Hamilton, Leeds, to which the second prize of the Association alluded to above was adjudged. This work has likewise been characterized by properties somewhat similar to those which have been applied to "The Great Commission," and the Author has been eulogized as a writer of great power and originality.—3. "*The Jubilee of the World*," by the Rev. J. Macfarlane, Minister of Colessie, published at the recommendation of four of the adjudicators of the Missionary Prize Essays—a volume which is justly considered as "the production of a well-disciplined mind, accustomed to think deeply and accurately on any subject to which its energies might be directed—that its tone and temper are decidedly evangelical, its spirit eminently catholic, and its appeals stirring and appropriate."—4. "*Christian Missions to Heathen Nations*," by the Honorable Baptist W. Noel, M. A. Though this volume is not considered equal to Mr. Macfarlane's in point of close argument and logical deduction, yet it has the advantage of it as a *practical* treatise on missionary work, and evinces a minute acquaintance with the whole scene of missionary labors, which, *in this respect*, is considered by some as superior to any of the other essays. Were these works carefully perused by the great mass of the Christian world, their spirit imbibed, and their practical suggestions carried into effect, the world would, ere long, be regenerated, and the dawn of the Millennial era would soon make its appearance

In fine, from the numerous *moral* facts which Geography unfolds, we learn the vast depth and extent of that moral degradation into which the human race has fallen—the ferocious tempers, and immoral practices, which are displayed in the regions of Pagan idolatry—the horrid cruelties, and vile abominations, that are daily perpetrated under the sanction of what is termed Religion—the wide extent of population over which the prince of darkness sways his scepter—the difficulties which require to be surmounted, before "the Gospel of salvation" can extend its full influence throughout the Pagan world—and the vast energies which are requisite to accomplish this glorious event. All these portions of information are calculated to confirm and illustrate the scriptural doctrine of the universal depravity of man—to exercise the faith of the Christian on the promises of Jehovah, in reference to the conversion of the benighted nations—to arouse his sympathies toward his degraded brethren of mankind, to excite his intercession in their behalf, and to direct his benevolence and activity, in devising and executing schemes for enlightening the people who are sitting "in darkness, and in the shadow of death."

GEOLOGY.

Another subject intimately related to the former, is the science of Geology.

This science has for its object, to investigate and describe the *internal structure* of the earth, the arrangement of the materials of which it is composed, the circumstances peculiar to its original formation, the different states under which it has existed, and the various changes which it appears to have undergone since the Almighty created the substance of which it is composed. From a consideration of the vast quantity of materials contained in the internal structure of our globe, and of the limited extent to which men can carry their operations, when they attempt to penetrate into its bowels, it is obvious that our knowledge of this subject must be very shallow and imperfect. The observations, however, which have been made on the structure of our globe during the last half century, and the conclusions deduced from them, are highly interesting both to the philosopher and to the Christian. Before the facts on which this branch of Natural History is founded, were accurately ascertained, various objections to the Mosaic history of the creation were started by certain skeptical philosophers, founded on partial and erroneous views of the real structure and economy of the earth; but it is now found, that the more accurately and minutely the system of nature is explored, the more distinctly do we perceive the harmony that subsists between the records of Revelation and the operations of the Creator in the material world. If both be admitted as the effects of the agency of the same Almighty and Eternal Being, they must, in the nature of things, completely harmonize, and can never be repugnant to each other—whether we be capable in every instance of perceiving their complete coincidence or not. If any facts could be produced in the visible creation which directly contradict the records of the Bible, it would form a proof, that the oracles which we hold as Divine were not dictated by the Creator and Governor of the Universe. But although some garbled facts have been triumphantly exhibited in this view; it is now ascertained, from the discoveries which have been lately made in relation to the structure and formation of the earth, that the truth of the facts detailed in Sacred History rests on a solid and immutable basis; and that the Supreme Intelligence who arranged the fabric of heaven and earth, and he alone, communicated to the inspired writers the doctrines and facts they have recorded: and we have reason to believe, that as Geologists proceed in their researches and investigations, still more sensible proofs of the authenticity of Revelation will be brought to light

Geology has of late become an interesting object of inquiry to the student of general science, and is now prosecuted with ardor by many distinguished philosophers. The observations which have been made in various parts of the world by late navigators; the facts which have been ascertained by Pallas, Saussure, De Luc, Humboldt, Lyell, Sedgwick, and other intelligent travelers; and the discoveries which have been brought to light by modern chemists and mineralogists, have all conspired to facilitate Geological inquiries, to render them more enlightened and satisfactory, and to prepare the way for future ages establishing a rational, scriptural, and substantial theory of the earth. The man who engages at such inquiries has always at hand a source of rational investigation and enjoyment. The ground on which he treads—the aspect of the surrounding country—the mines, the caves, and the quarries which he explores—every new country in which he travels, every mountain he climbs, and every new surface of the earth that is laid open to his inspection, offer to him novel and interesting stores of information. On descending into mines, we are not only gratified by displays of human ingenuity, but we also acquire views of the strata of earth, and of the revolutions it has undergone since the period of its first formation. Our researches on the surface of the earth, amidst abrupt precipices and lofty mountains, introduce us to the grandest and most sublime works of the Creator, and present to our view the effects of stupendous forces, which have overturned mountains, and rent the foundations of nature. "In the midst of such scenes, the Geologist feels his mind invigorated; the magnitude of the appearances before him extinguishes all the little and contracted notions he may have formed in the closet; and he learns, that it is only by visiting and studying those stupendous works, that he can form an adequate conception of the great relations of the crust of the globe, and of its mode of formation."*

At first sight, the solid mass of the earth appears to be a confused assemblage of rocky masses, piled on each other without regularity or order, where none of those admirable displays of skill and contrivance are to be observed, which so powerfully excite attention in the structure of animals and vegetables. But on a nearer and more intimate view, a variety of beautiful arrangements has been traced by the industry of Geologists, and the light of modern discoveries: by which they have been enabled to classify these apparent irregularities of nature. The rocks of which the crust of the earth is chiefly composed, occur in beds or layers, each of which is distinguished by its peculiar characteristic. 1. The first class is what has been denominated PRIMARY ROCKS. These constitute the great frame-work, or primitive envelope of the globe. They form the most lofty mountains, and at the same time extend downward below all the other formations to the greatest depths yet penetrated by man, and constitute everywhere the foundation on which the other rocks are supported. It is, therefore, supposed that they were the earliest formed, in the progress of creation; and are hence denominated *primitive* or *primary* rocks. One of the principal rocks of this class is *granite*, which is compounded of *quartz*, *feldspar*, and *mica*. *Gneiss*, or slaty granite, is considered as another species; and *mica slate* a third species of the primitive rocks. There are some other primary rocks which occur imbedded in, and interstratified with the principal primitive rocks. They are called *subordinate rocks*, and are named as follows:—*Hornblende* rock, *Serpentine*, *Crystalline Limestone*, *Quartz* rock. The three principal rocks of this class, granite, gneiss, and mica slate, might with propriety be regarded as belonging to one formation. They are composed *essentially* of the same minerals, varying in different proportions, and are rather modes of the same rock than different species. They pass by gradations into each other, as one or other of their constituent minerals becomes more or less abundant; they alternate with each other in various situations, and may be regarded as contemporaneous.—Granite is considered as the foundation rock, on which slate and all secondary rocks are laid. When granite rises above the surface, the beds of other rocks in the same district rise toward it, and lie against it, as in fig. 15; but there are instances in which they appear to pitch under the granite, as in the next figure. The aspect of granite mountains is extremely various. When the beds are horizontal, or when the rock is soft and disintegrating, the summits are rounded and unpicturesque. (See fig. 16.) When hard and soft granite occur in the same mass, the soft decomposes, and leaves the hard in large, loose masses upon the soil, or if they lie in alternate and highly inclined beds, the hard granite forms high and almost inaccessible peaks, as seen in fig. 17.

---

Fig. 15.

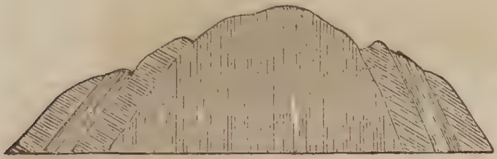

Fig. 16.

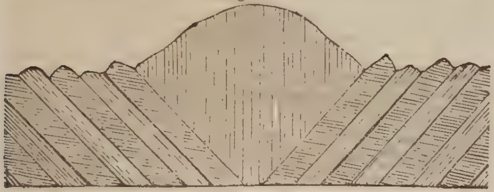

Fig. 17.

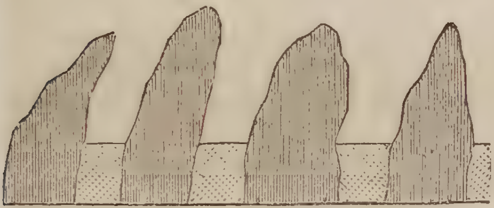


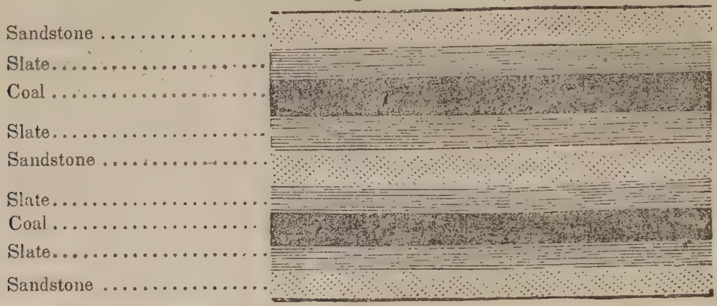
The structure of primary rocks is *crystalline*—(see fig. 17), they form the central parts of the most elevated mountain-chains —they never contain the fragments of other rocks—and they are particularly distinguished from all other formations in this,—that *they contain no remains of organized substances*. There also appears conclusive evidence, that materials composing granite, of which this class of rocks chiefly consists, were once in a state of fusion

2. The class of rocks next in order to the primitive are what are termed Transition Rocks,—which are next and above the primitive on which they rest. This formation is composed of the larger fragments of all the primitive rocks consolidated into continuous masses. It is supposed that these rocks were formed, when the primary rocks were thrown up from the bed of the primeval ocean, when the disruptions caused by such powerful and mighty movements, reduced the higher parts of the primitive to fragments. These shattered fragments becoming agglutinated by their own pulverent cement, recomposed continuous strata which form the rocks to which we allude. In this class of rocks we first behold the rudiments of vitality—the dawn of organization —the first-born of earthly creatures, whose existence is recorded in imperishable characters. These consist of organized beings of the lowest orders, such as sea-shells of various descriptions, which are here found imbedded, and which afford a decisive evidence that such rocks were formed *after* the creation of organized beings—the rocks belonging to this class are *Transition* or mountain limestone—*Graywacke*, and graywacke slate—*Slate* and its varieties. Roof-slate, and the slate of which school slates are made, are well known varieties of this rock. It is sometimes called *clay-slate*, argillaceous slate, and argillaceous schistus. Transition rocks are the principal repositories of metallic ores, which occur both in beds and veins more abundantly in many of the rocks of this class than in primary rocks.

3. The next class is the Secondary Rocks, which lie upon the transition rocks, and appear like deposits composed of grains which once belonged to primitive rocks. Geologists now divide these rocks into *upper* secondary and *lower* secondary. The principal secondary formations are: (1.)—The *coal* formation, in the lower secondary series, and the rock-salt or saliferous formation in the upper secondary. The strata of the coal formation are numerous, extensive, and parallel; but they are often beset, undulating, curved, broken, and contorted in various ways. The strata connected with the coal bear evidences, in some instances, of having been rapidly deposited, as in the cases where we find the vertical stems of plants standing in their natural position, in many coal mines, and the rocks deposited around them in horizontal or slightly inclined strata. The stems of arborescent plants, two or three feet in diameter, are thus found piercing through the strata many feet. In such a case, the sand mud must have been deposited within a comparatively short time around them, otherwise in a climate such as that in which these plants grew, they would have decayed and left no indications of their existence. —Coal occurs in regular strata which vary in thickness from a few inches to several feet or yards. In the same coal formations many strata of coal occur under each other separated by a stratum of shale, sandstone, etc. The series of strata which occur together is called a *coal field*

Coal fields are of limited extent, and the strata often dip to a common center, being often arranged in basin-shaped cavities, which appear to have been originally detached lakes that were gradually filled up by repeated depositions of carbonaceous and mineral matter. The different strata over and under the beds of coal are frequently similar, and the same series of strata is repeated for each successive stratum of coal, as shown in fig. 18. Coals are generally supposed to have had a *vegetable* origin; and, when we consider the abundance of vegetable remains usually found in connection with coal, and the vegetable structure which the coal itself sometimes exhibits, we can hardly doubt as to its origin. At most coal mines, even the thinnest layers of slate, when split off, show the impressions of the leaves and flat stems of the various grasses, reeds, and ferns, in all their most delicate parts. The impressions between the layers of slate sometimes give as perfect a representation of the plant, as if the plant had been pressed and dried in a book, and the leaves then opened to display it.

Fig. 18.



(2.) The *upper* secondary rocks comprise all the different formations above the great coal formations, to the upper limit of the chalk series. These rocks are divided into the three following formations. 1. *Chalk*, or cretaceous rocks, including the ferruginous and green sand. 2. *Oolitic Rocks*, lias limestone, and lias clay. 3. *Red Sandstone*, including magnesian limestone.—The red sandstone formation is characterized by the first appearance of the remains of the *Saurian*, or lizard-shaped animals. The remains of a number of species have been found, differing in their appearance from the crocodile and alligator, some of which must have been from 60 to 120 feet in length. These animals appear to have lived in salt water, unlike any of this class with which we are acquainted at the present day, all of which belong either to the land or to fresh water. They had neither feet nor fins, but paddles like the sea turtle, and their tails were long, of the form of an oar, and fitted to propel them through the most agitated waters. The *Oolitic* rocks are composed of various strata of limestone, clay, sand, and sandstone. *Oolite* derives its name from the small globules that are imbedded in this species of rock—some of the masses of which appear composed of little rounded globules like the *roes* of fish. These rocks are remarkable for the great variety of organic remains they contain. The animal remains are those belonging to the land, and to fresh water. The teeth and bones of fish and reptiles are abundant. The reptiles are mostly *saurian* animals and turtles. Among these are the Megalo saurus, the Plesio saurus, and the Iguanodon, some of which must have been at least 70 feet in length, and of the hight of an elephant. There are also *vegetable* fossils in these rocks,—consisting of arborescent forms, trunks of palms, gigantic reeds, and similar vegetable productions, which are now to be found growing only in the Torrid Zone.

4. The next division is the Tertiary, which is considered as having been deposited after the Secondary. The strata comprehended under this class consist of beds of clay, marl, sand, pudding-stones, and imperfectly consolidated limestone, which appear to have been deposited since the chalk formation. The tertiary deposits contain no beds of minerals or metallic veins, capable of exploration, except lignite and jet, which are used for fuel and ornament,—clay for pottery, sand for the manufacture of glass, pyrites for the manufacture of copperas and alum, and a valuable iron ore called hydrate of iron. This formation, however, abounds with a vast quantity of vegetable and animal remains, such as crocodiles, crabs, lobsters, several species of vertebral fish, and a vast number of testaceous exuviæ; so well preserved as to have the appearance of recent shells. The most remarkable discovery that has been made respecting the Tertiary deposits is, that many of them contain the bones of *mammiferous animals* (that is those which suckle their young) as perfect in their organization as any of the exising species of land animals; but most of them belong to genera or species that are extinct. These strata are further remarkable for presenting the frequent alternation of beds containing the remains of marine animals, with other beds that contain the bones of land animals or fresh water shells. The city of Paris, in France, and the country around, which are situated upon a tertiary deposit, which rests upon chalk—are remarkable for the extraordinary organic remains which they contain. Millions of marine shells compose the principal mass. Bones of marine animals, of which the genera are entirely unknown, are found in certain parts. Other bones, remarkable for their vast size, and of which some of similar genera exist only in distant countries, are found scattered in the upper beds. Not only the remains of sea animals and land quadrupeds, but also those of birds, are found in this deposit, such as the duck, the pelican, the woodcock, the starling, and the skylark. The famous locality of fossil fish at Monte Bolca, in Italy, is in tertiary strata. About 105 species have been found in those quarries, and many of them are different from any species known to exist in the neighboring seas, or even in any part of the earth.

5. The next distinction of formations made by Geologists is Diluvial and *Alluvial* deposits—the former being generally considered as having been formed by the last general deluge, and the latter by currents of rivers and other causes now in

operation. The blocks of rock and the beds of gravel spread or scattered on the surface of the ground, composed of stone or fragments foreign to the district in which they are spread, and which frequently cover the bones of unknown species of quadrupeds — are called *Diluvial* depositions, that is, depositions which have been caused by a deluge The materials of these deposits are usually coarse, and composed of gravel, pebbles, and blocks of a great variety of rocks aggregated without any regularity. The sand, soil, or fragments brought down by rivers, and spread along their banks or at their mouths, are called *alluvial* depositions. The bones and skeletons of large animals, and especially the *Mammoth*, are found in diluvial gravel in many countries. In Siberia, the tusks of the fossil elephant are found in the diluvial banks of almost every river, and sometimes in such abundance that the ivory from these skeletons is an article of export. It is said that the skeleton of a whale lies on the top of mountains 3000 feet high on the coast of the Northern ocean, which could scarcely have been conveyed to such an elevation but by an immense overwhelming deluge.

Alluvial deposits are the most superficial of all the formations; they are forming every day; they envelop the remains of animals that still exist on the surfaces they have formed, and they are also mingled with the remains of animals which have existed in recent times. The alluvial beds, taken as masses, are all of loose earth, and are never covered by rocky masses; and in these beds chiefly are to be found the remains of human beings and the monuments of their industry and art. There is a constant tendency in torrents, currents, rivers, tides, winds, and similar causes, to wear down the inequalities of the land and deposit the materials in the sea. In this way *deltas* have been formed, such as the deltas of the Nile, the Ganges, the Mississippi, the Danube, and the Rhone. The mouths of the Mississippi are now more than 100 miles from its original entrance into the gulf of Mexico, and for hundreds of miles above most of the land seen from its banks is alluvial; so that all the mass of land alluded to has been formed by materials carried down by the rapid current of this mighty river. The delta of the Ganges commences 220 miles in a direct line from the ocean; and the town of Adria, which was once a port on the Adriatic, is now 20 miles inland; all which vast accumulations are considered as the effects of Alluvial depositions.

6. There is likewise a species of Rocks distinguished by Geologists by the title of Volcanic and Basaltic rocks; which owe their origin to volcanic fire, and are sometimes forced up to the surface of the earth by the action of subterranean heat. The principal volcanic rocks are *basalt*, *lava*, and *greenstone*. Volcanic rocks occur in shapeless masses, and are destitute of organic remains. In some parts of Europe, as in Iceland, Sicily, and the country around Naples, active volcanoes still exist, which frequently emit vast quantities of lava, ashes, and other species of matter But even in places where no active volcanoes exist, as in Auvergne, Velay, and Vivavais, in France, several hundreds of conical hills are found, with craters near their summits. These hills are composed of materials similar to those of active volcanoes, and streams of lava may sometimes be traced proceeding from the cones into the adjoining valleys, where they choke up the ancient channels of rivers, in the same manner as some of the modern lavas in Iceland have been known to do, the rivers either flowing beneath, or cutting out a passage on one side of the lava.—Trap rocks are related to volcanic, and are mostly composed of hornblende and feldspar. The term *trap* is derived from the German word *trappa*, a stair, as many of these rocks occur in a terrace form, or like the steps of a stair—a configuration which is supposed to be owing to the stopping of large sheets of lava when flowing, whether at the bottom of the sea or on dry land; for it is known that streams of lava generally terminate in abrupt precipices, similar to the beds constituting the trap ranges. These rocks are distinguished, even at a distance, from those of the stratified formations, as they occur in shapeless masses, and form hilly tracts of great irregularity of surface, or in the form of walls or *dykes* penetrating other rocks, which they alter in character to a certain degree at this point of contact.

Basalt is of a black or bluish-gray color. It is commonly fine-grained, and consists of an intimate admixture of feldspar and augite, a variety of hornblende, with some oxyd of iron. Many of the Western Islands of Scotland are wholly or almost composed of basalt. The island of *Staffa* is a complete mass of basalt. It is about two miles in circumference, and is surrounded on every side by steep cliffs, 70 feet high, formed of clusters of angular columns, containing from 5 to 7 sides each. Fingal's cave is in the S. E. corner of the island, and presents a magnificent chasm, 42 feet wide, and 227 in length. The roof, which is 100 feet high at the entrance, gradually diminishes to 50, and is composed of the projecting extremities of basaltic pillars, and the base of a causeway of the same materials.—The *Giant's Causeway*, in the county of Antrim, in Ireland, is another striking specimen of basaltic columns. It consists of hundreds of thousands of pentagonal and hexagonal columns (that is, columns of 5 and 6 sides) varying from 1 to 5 feet in thickness, and from 20 to 200 feet in hight. The district in which this remarkable formation occurs lies on both sides of the river Bann, and comprehends an area of 800 square miles.—Throughout this area, the basalt is found occupying all the eminences, and constituting an overlying bed of igneous rocks, at least 500 feet in thickness. The greatest mass of basalt yet known occurs in the province of Deccan in India, where it constitutes the surface over an area of many thousand square miles.

Having given the above brief sketches of the different orders of stratification, I shall conclude this department of the subject, by a few general statements respecting the organic remains imbedded in the several formations to which we have adverted.

1. Organic remains are not found promiscuously scattered through the rocks, but each formation has its peculiar group of animals and plants; and on comparing together the larger groups of strata, we find scarcely any organic remains common to any two of them. These fossil animal and plants are found together in groups, very much as living plants and animals are—different groups occupying different portions of the surface of the earth and of the ocean. Hence it is concluded, that these remains were once living plants and animals, which, in different periods, occupied the ocean and the dry land, grouped together as we now find them, and that, as they died, they became enveloped in rock, near the places where they passed their existence.

2. Some of the formations and deposits to which we have alluded, particularly the *Mountain limestone*, consist almost entirely of the shells and co-

ralline productions of sea animals, and this formation is often a thousand or more feet in thickness, and many miles in length and breadth. In what are termed the *Silurian* formations is found a long succession of strata many thousand feet in thickness, and imbedding not fewer than 375 species belonging to the animal kingdom.

3. It is considered as an established fact, that of more than 3000 species of plants and animals that are found in a fossil state in the secondary rocks, not a single species corresponds with any now living on the globe; and even out of 3000 fossil species in the Tertiary formation less than 600 are identical with living species. In short, in all the different formations, until we come to the uppermost and the newest, the thousand species they contain are all different from any in the now existing creation, though possessing family analogies.

4. It is a remarkable fact, that notwithstanding the great variety of fossils observed in the early formations, the remains of *Man* are not to be found in these formations. The remains of human beings and the vestiges of the arts and operations of man are discovered only in or upon those earthly masses which are demonstrably posterior to all regular geological deposits—or, the Diluvial and Alluvial formations—and under circumstances indicating the human species to have been among the recent productions of the Creator's power, and that man was created at a period posterior to those great changes and convulsions which destroyed so many millions of millions of animated beings. Had this not been the case, it is almost certain that numerous remains of the human species would have been found in the early formations.

"The phenomena of Geology show that the original formation of the rocks has been accompanied, in nearly all its stages, by a process of waste, decay, and recomposition. The rocks, as they were successively deposited, were acted upon by air and water, heat, etc., broken into fragments or worn down into grains out of which new strata were formed. Even the newer secondary rocks, since their consolidation, have been subject to great changes, of which very distinct monuments remain. Thus, we have single mountains, which from their structure can be considered only as remnants of great formations, or of great continents no longer in existence.—Mount Meisner, in Hesse, six miles long, and three broad, rises about 1800 feet above its base, and 2100 above the sea, overtopping all the neighboring hills for 40 or 50 miles round. The lowest part of the mountain consists of the same shell, limestone, and sandstone, which exist in the adjacent country. Above these are, first, a bed of sand, then a bed of fossil wood 100 feet thick at some points, and the whole is covered by a mass of basalt, 500 feet in hight. On considering these facts it is impossible to avoid concluding, that this mountain which now overtops the neighboring country, occupied at one time the bottom of a cavity in the midst of the higher lands. The vast mass of fossil wood could not all have grown there, but must have been transported by water from a more elevated surface, and lodged in what was then a hollow. The basalt which covers the wood must also have flowed in a current from a higher site; but the soil over which the basalt and the wood passed has been swept away, leaving this mountain as a solitary memorial to attest its existence. Thus also on the side of Mount Jura next the Alps, where no other mountain interposes, there are found vast blocks of granite (some of them of 1000 cubic yards) at the hight of more than 2000 feet above the lake of Geneva. These blocks are foreign to the rocks among which they lie, and have evidently come from the opposite chain of the Alps; but the land which constituted the inclined plane over which they were rolled or transported has been worn away, and the valley of Lower Switzerland, with its lakes, now occupies its place. Transported masses of primitive rocks of the same description are found scattered over the north of Germany, which Von Buch ascertained, by their characters, to belong to the mountains of Scandinavia; and which therefore carry us back to a period when an elevated continent, occupying the basin of the Baltic, connected Saxony and Norway."*

The production of a bed for *vegetation* is effected by the decomposition of rocks. This decomposition is effected by the expansion of water in pores or the fissures of rocks, by heat or congelation, by the solvent power of moisture, and by electricity, which is known to be a powerful agent of decomposition. As soon as the rock begins to be softened, the seeds of *lichens*, which are constantly floating in the air, make it their resting-place. Their generations occupy it until a finely divided earth is formed, which becomes capable of supporting mosses and heath; acted upon by light and heat, these plants imbibe the dew and convert constituent parts of the air into nourishment. Their death and decay afford food for a more perfect species of vegetable; and at length a mold is formed, in which even the trees of the forest can fix their roots, and which is capable of rewarding the labors of the cultivator.—The decomposition of rock tends to the *renovation* of soils, as well as their cultivation. Finely divided matter is carried by rivers from the higher districts to the low countries, and alluvial lands are usually extremely fertile. By these operations the quantity of habitable surface is constantly increased; precipitous cliffs are gradually made gentle slopes, lakes are filled up, and islands are formed at the mouths of great rivers; so that, as the world grows older, its capacity for containing an increased number of inhabitants is gradually enlarging.

Of all the memorials of the past history of our globe, the most interesting are those myriads of remains of organized bodies which exist in the interior of its outer crusts. In these, we find traces of innumerable orders of beings existing under different circumstances, succeeding one another at distant epochs, and varying through multiplied changes of form. "If we examine the secondary rocks, beginning with the most ancient, the first organic remains which present themselves are those of aquatic plants and large reeds, but of species different from ours. To these succeed madrepores, encrenites, and other aquatic zoophites, living beings of the simplest forms, which remain attached to one spot, and partake, in some degree, of the nature of vegetables. Posterior to these are ammonites, and other mollusci, still very simple in their forms, and entirely different from any animals now known. After these, some fishes appear; and plants, consisting of bamboos and ferns, increase, but still different from those which exist. In the next period, along with an increasing number of extinct species of shells and fishes, we meet with amphibious and viviparous quadrupeds, such as crocodiles and tortoises, and some reptiles, as serpents, which show that dry land now existed. As we approach the newest of the solid rock formation, we find lamantins, phocæ, and other cetaceous and mammiferous sea animals, with some birds. And in the newest of these formations, we find the remains of herbiferous land animals of extinct species, the paleotherium, anaplotherium, etc., and of birds, with some fresh water shells. In the lowest beds of loose soil, and in peat bogs, are found the remains of the elephant, rhinoceros, hippopotamus, elk, etc., of different species from those which now exist, but belonging to the same genera. Lastly, the bones of the species which are apparently the same with those now existing alive, are never found except in the very latest alluvial depositions, or those which are either formed in the sides of rivers, the bottom of ancient lakes and marshes now dried up, in peat beds, in the fissures and caverns of certain rocks, or at small depths below the present surface, in places where they may have been overwhelmed by debris, or even buried by man. Human bones are never found except among those of animal species now living, and in situations which show that they have been, comparatively speaking, recently deposited."*

---

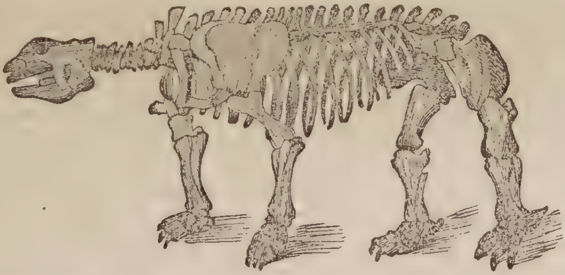
* Supplement to the Encyclopædia Britannica, 6th edit vol. vi.

Numerous species of animals have been found imbedded in the secondary strata—no living examples of which are now to be found in any quarter of the globe. Among the most remarkable of these are the following:—1. The *Mammoth*, which bears a certain resemblance to the elephant, but is much larger, and differs considerably in the size and form of the tusks, jaws, and grinders. The fossil remains of this animal are more abundant in Siberia than in other countries; there being scarcely a spot, from the river Don to Kamtschatka, in which they have not been found. Not only single bones and perfect skeletons of this animal are frequently to be met with; but, in a late instance, the whole animal was found preserved in ice. This animal was discovered on the banks of the frozen ocean, near the mouth of the river Jena, in 1799; and in 1805, Mr. Adams got it conveyed over a space of 7000 miles to Petersburg, where it is deposited in the museum. The flesh, skin, and hair, were completely preserved, and even the eyes were entire. It was provided with a long mane, and the body was covered with hair. This hair was of different qualities. There were stiff black bristles from twelve to fifteen inches long, and these belonged to the tail, mane, and ears. Other bristles were from nine to ten inches long, and of a brown color; and beside these, there was a coarse wool, from four to five inches long, of a pale yellow color. This mammoth was a male; it measured nine feet four inches in hight, and was sixteen feet four inches long, without including the tusks. The tusks, measuring along the curve, are nine feet six inches; and the two together weigh 360 lbs. avoirdupois. The head alone, without the tusks, weighs 414 lbs. avoirdupois. The remains of this animal have been found likewise in Iceland, Norway, Scotland, England, and in many places through the continent onward to the Arctic ocean.

2. The *Megatherium*. A complete skeleton of this colossal species was found in diluvial soil near Buenos Ayres, and sent to Madrid. The specimen is fourteen feet long, and seven Spanish feet in hight.

3. The Great *Mastodon* of the Ohio, of which the following figure is a representation. This species appears to have been as tall as the elephant, but with longer and thicker limbs. It had tusks like the elephant, and appears to have lived on roots. Its remains abound in America, particularly on the banks of the Ohio.

Fig. 19.



4. The *Tapir*, which also abounds in America. The one named *Gigantic Tapir*, is about eighteen feet long, and twelve feet high.

5. The *Irish Elk*, or Elk of the Isle of Man. This gigantic species, now apparently extinct, occurs in a fossil state, in Ireland, Isle of Man, England, Germany, and France. The most perfect specimen of this species, which was found in the Isle of Man, may be seen in the museum of the University of Edinburgh. It is six feet high, nine feet long, and in hight, to the tip of the right horn, nine feet seven and a half inches.†

Such are a few of the facts which the researches of modern Geology have disclosed. Let us now consider what are the conclusions which have been deduced from them.

One of the grand conclusions which has been deduced by modern geologists—even by those who acknowledge the divinity of the Christian Revelation, is, that *the materials of which our globe is composed are of very high antiquity*, and were brought into existence long before the race of Adam was placed upon the earth. The exact period of years which any of these materials may have existed, or any approximation to it, no geologist has yet undertaken to determine, nor is it likely that the problem will ever be satisfactorily solved. In reference to some of the coal strata, Mr. Macculloch, in his "System of Geology," states that it would be even too short a period "were we to allow 200,000 years for the production of the coal mines of Newcastle with all its rocky strata," not including the subsequent formations up to the present condition of the earth. Mr. Maclaren, in his "Geology of Fife and the Lothians," estimates a single period of volcanic quiescence, during which strata of coal, shale, sandstone, and limestone, were deposited over the side of Arthur's Seat, a basaltic hill in the vicinity of Edinburgh—at *five hundred thousand years.* Mr. Babbage, when referring to the tertiary class of formations, regards it as a truth, supported by irresistible evidence, "that the formation even of those strata which are nearest the surface, must have occupied vast periods, probably *millions* of years."* The Rev. Professor Sedgwick, when adverting to the process of forming deposits, says, that "a section of a few perpendicular feet indicates *a very long* lapse of time," so that in such processes "many thousands of years sink into a trifling period." In short, the most respectable modern geologists, when alluding to this point, use such expressions as the following—"immense periods of time"—"a duration to which we dare not assign a boundary"—"undefined ages"—"a long succession of monuments, for the production of each of which there may have been required a thousand ages"—"successions of events, where the language of nature signifies millions of years"—"a duration which it would be presumptuous to put into an estimate of years and centuries"—with many other expressions of a similar import. Whether such strong and unlimited expressions be warranted by the nature of the processes alluded to, I do not take upon me to determine.

* Sup. to Encyc. Brit., vol. vi.

† An Engraving of this skeleton may be seen in Vol. Sixth of Sup. to Encyc. Brit., 6th edit.

2. Another conclusion which has been deduced from the above stated facts, is, that during the changes which the globe has undergone, since its original production out of nothing, *several destructions and subsequent new creations of animals and plants have taken place,* perhaps at very different and very distant epochs. The greater part of geologists conclude, that four or five distinct epochs of destruction and renewal may be traced in the organic remains contained in the different strata; in other words, that whole groups have been swept at once from existence by some powerful catastrophe, and their places supplied by other races, called into existence by the creating energy of the Almighty. The records of geology seem to testify that such was the condition of the globe, in those early periods, as to temperature and other circumstances, that our present races of animals could not have then existed, and that such was the nature and constitution of these primeval beings, that they could not exist in the present constitution and circumstances of our globe; their natures being adapted to the different conditions of the earth, at different periods of its existence.

3. A third conclusion is, that *the successive changes to which our globe has been subjected, have been improvements in its condition as a habitable world,* that there has been a correspondent advance toward perfection in the natures of the animals and plants which have been placed upon its surface; and that *the Deity, during this long period of successive changes, was gradually fitting up this world for the ultimate residence of moral and intellectual beings,* such as the human species that now inhabit it. For it appears next to certain that the race of man could not have inhabited this globe in any of the past periods of its duration, prior to that era in which he was placed upon it. It would appear that the Deity did not think proper to prepare a suitable habitation for man by a *miracle*, or a direct interposition of his Almighty energy, but by the agency of those physical laws which he had impressed upon the elementary principles of the material universe. And in order that matter might not exist in vain, myriads of brings were brought into existence, under the direction of Infinite Wisdom, endowed with faculties and natures adapted to those peculiar states of the terraqueous globe in which they were to pass their existence.

Such are a few of the facts connected with the constitution of our globe, and the conclusions which have been deduced from them. It now remains that we inquire into their accordance with the records of the Sacred history.

It has been too frequently taken for granted by theologians and commentators, that the whole system of the material universe was brought into existence within the period of 6000 years from the present time; and hence, some of them who have been anxious to reconcile the Mosaic and Geological chronologies, have attempted to show that all the formations and changes in the strata of the earth, to which we have alluded, might have been effected within the period of 6000 years, and particularly during the continuance of the deluge in the days of Noah. Some of them have insinuated that the *coralline reefs,* which exhibit vast accumulations of calcareous matter, and which abound on the coast of New Holland, and among the islands of the Pacific ocean, have been all formed since the present order of things commenced; and therefore that all the other formations to which we have already alluded, even the oldest, may have been formed within the same period. It has also been insinuated, that it appears derogatory to the Wisdom and Power of the Creator to suppose, that for thousands of years the earth should have been occupied merely with vegetables and animals of the lowest orders, and that many species of each class were alternately created, and permitted to retire out of existence.

But such positions are now considered as absolutely untenable by all the most scientific and respectable geologists of modern times, as being inconsistent with facts that are everywhere perceptible in the strata of our globe. As to the designs which the Almighty had in view, in replenishing the earth for so long a period of time, chiefly with the inferior ranks of existence, and again permitting them to perish, it becomes us to speak with reverence and humility, as beings whose faculties are limited, and altogether inadequate to trace the inscrutable paths of the Divinity, or to investigate the reasons of every part of his procedure. We cannot, in many cases, decide as to what is consistent or inconsistent with the attributes of the Almighty; and, in the present case, as well as in many others, we must admit that the operations of the Deity are unsearchable, and "his ways past finding out." "Canst thou by searching find out the secrets of God? Canst thou find out the designs of the Almighty? they are as high as the heavens, deeper than hades; the measure thereof is longer than the earth and broader than the sea." But this we know that, in consequence of the previous revolutions which our globe has undergone, it was prepared for being a suitable habitation for the human species, and for the other ranks of animated nature that now possess it; and although some portions of it present the appearance of desolation and disarrangement, yet were man its chief inhabitant, renovated in the spirit of his mind, and found acting on the moral principles of Christianity, in the capacity of communities and nations, it might soon be cultivated and renovated throughout all its extent, so as to present the aspect of a terrestrial paradise, and to shine forth with all the beauties of Eden.

---

* Babbage's Ninth Bridgewater Treatise.

But, to come more particularly to the subject in hand. Had Moses, in his history of the Creation, positively declared that every portion of the material world was created out of nothing, within 1650 years of the period of the deluge, or about 6000 years ago, it would be difficult, if not impossible, to reconcile the facts of geology with the Mosaic history. But no such position is to be found either in the writings of Moses or throughout any other portion of sacred Scripture. For the illustration of this point, it may be proper for a little to consider the meaning and import of the 1st verse of the first chapter of Genesis: "*In the beginning God created the heavens and the earth.*"

This proposition is to be considered as a *Preface* to the following narrative of the arrangements connected with our terrestrial system, and, indeed, to the whole of Divine Revelation; and a more comprehensive, emphatic, and *appropriate* introduction can scarcely be conceived. By *the heavens and the earth*, we are here undoubtedly to understand the whole frame of the material universe, with all the bodies it contains, wherever existing throughout immensity—whether suns, planets, comets, nebulæ, or whatever else exists throughout the regions of boundless space. All the bodies comprehended under this general expression are here said to have been *created*, that is, brought from nothing into existence by the energy of an Eternal and Omnipotent agent. The original Hebrew word, *Bara*, does not indeed necessarily convey this idea, as it most frequently signifies "to produce something new or wonderful," or "to arrange, to renovate, or new-model" something which was previously in existence. It is a matter of rational inference, however, and strictly accordant with just philosophical principles, that the material universe was *created out of nothing.* It is such an inference as cannot be resisted without doing violence to the fundamental laws of human belief. This magnificent frame of the universe is here said to have been brought into existence by God, the God of Israel, the Self-existent and Eternal Jehovah. This declaration was intended to teach the Israelites, and all others, that the material world as to its original atoms, did not arise without a cause, or out of pre-existent materials; that the beautiful order it now exhibits did not originate from the fortuitous concourse of atoms, as some heathen philosophers imagined, and that it did not derive its existence from any of the gods of the nations, as some of their blinded worshippers foolishly imagined. In opposition to all such chimerical, absurd, and atheistical notions, Moses declares, "In the beginning God"—the God of Israel—"created the heavens and the earth." As if he had said, That God who delivered you from the land of Egypt, after having displayed so many signs and wonders; who divided the waters of the Red sea before you, and who appeared in awful majesty at Mount Sinai; that God whom you are commanded to worship, and whose laws you are bound to obey—is the Great Being who reared that wonderful fabric of heaven and earth which your eyes behold.

The *period* when this astonishing effect was produced is also here declared, "*In the beginning.*" Upon a proper conception of the meaning of this expression depends, in a great measure, the reconciliation of the geological and the Mosaic chronology. The phrase here stated, "In the beginning," is used to denote the commencement of an era, or of a series of successive events. It evidently implies that, at what period soever in the long lapse of past duration, any part of the material creation was brought into existence, it derived that existence from the Self-existent and Eternal Divinity. But no specific period is here stated. Had Moses expressly told his readers that this period, when the first materials of creation were brought into existence, was about 2500 years from the time in which he wrote, then there would have been an almost insuperable difficulty in reconciling the discoveries of geology with such a statement. But no such assertion, either directly or by implication, is to be found throughout the whole range of Divine revelation. Ten thousands of years, or even millions of ages, may have elapsed since the first portions of matter were created, or previous to what is termed the first day's work, in the arrangements of our globe,—for anything that the Scripture asserts to the contrary. No limit is fixed to the time which may have elapsed between the period when the component materials of our globe were created, and the period when it began to be reduced into the order in which we now behold it; and no information is given as to the events which may have occurred during this interval. For it appears to have been the chief design of the Sacred Historian to give a narration of those events which were introductory to the placing of man upon the earth. And in this point of view it is important to remark, that the passage before us is entirely independent of the narrative of the six days' work which follows, and is to be considered simply as a general and most important truth, forming an appropriate introduction both to the following narrative and to the whole system of Revelation.

It is therefore to be regretted that certain theologians should still persist in maintaining that the whole material creation must be limited to a period within 6000 years from this date, when Scripture is silent on this point; for in so doing they put an argument into the hands of the philosophical infidel, which it is in his power to wield against the truth and authority of Revelation.

If the propriety of the explanation now given be admitted, then it completely removes every objection against the Mosaic record, derived from the supposed antiquity of the earth. Although it could be proved that some of the strata of our globe were formed millions of ages ago; although we should conceive what is neither impossible, nor altogether improbable—that our globe, in another form, has been the abode, for thousands of ages, of intellectual beings analogous to man, who are now transported to another region of creation —or that it has been the habitation of numerous and diversified races both of sentient and intellectual natures, and that millions of millions of ages have rolled on since the Creator put forth his Omnipotent energy, and since such stupendous revolutions commenced—neither of such views is in the least discordant with any doctrine or fact recorded in the sacred oracles. The Psalmist declares in reference to creation, when addressing the Almighty, "OF OLD hast thou laid the foundations of the earth, and the heavens are the works of thy hands;" and the Apostle Paul declares, "Thou Lord, IN THE BEGINNING, hast laid the foundations of the earth." But no specific period is stated here, or in any other portion of Scripture; and the expression OF OLD is not only correspondent with what we have now stated, but seems to imply the idea of the high antiquity of the earth.

The circumstance now adverted to—that Moses specifies no definite period as the commencement of the material creation—I consider as a corroborative argument for the truth of Divine Revelation. Had he written at random, or from vague tradition, or had he intended merely to give play to an exuberant fancy, in describing what no uninspired mortal could ever have known—it is not likely he would have used language so cautious and appropriate, as not to have interfered with any subsequent discoveries that might be made in the constitution of the material universe. Among all the cosmogonies which have been composed by heathen writers, either from tradition or from their own fancies, there is not one which accords with the discoveries of modern times; but, on the contrary, they all contain statements in direct opposition to facts which are known to exist in the material system. But the inspired writers were—perhaps unconsciously to themselves—directed to use such language as, when rightly interpreted, would be quite consistent with all the views and discoveries that might be opened of the works of God to the latest generations.

It has been supposed by some who cannot be persuaded to admit the notion of the high antiquity of the earth, that the rocks, with all the fossil petrifactions they contain, were created just as we find them, in a moment of time. "The Divine Being," they affirm, "might as easily have made matter to assume the form of a shell, a fish, a lizard, or a water-worn pebble, such as we find in these rocks, or of any other shape or structure." To all who have bestowed the least attention on the strata of the earth and their fossil remains, such statements and reasonings must appear foolish and absurd in the highest degree. To use the words of Professor Silliman: "We will not inquire whether Almighty Power inserted plants and animals in mineral masses, and was thus exerted in working a long series of useless miracles without design or end, and therefore incredible. The man who can believe, for example, that the Iguanodon, with his gigantic form, 70 feet in length, 10 in height, and 15 in girth, was created in the midst of consolidated sandstone, and placed down 1000 or 1200 feet from the surface of the earth, in a rock composed of ruins and fragments, and containing vegetables, shells, fish, and rolled pebbles—such a man can believe anything, with or without evidence. If there be any such persons, we must leave them to their own reflections, since they cannot be influenced by reason and sound argument; with them we can sustain no discussion, for there is no common ground on which we can meet."

But why, I would ask, should the idea of the high antiquity of the earth frighten any persons from acquiescing in it, when it is not in the least repugnant to the declarations of Scripture? So far from contracting or distorting our views of the Divine perfections, it tends to expand our conceptions of the plans and operations of the Deity. If periods of duration almost too great for human powers to estimate, have been employed since the original creation of our globe, to bring it to its present state,—if vast successive revolutions, at different eras, have taken place upon its surface—if the waters of the mighty deep have at different periods overflowed the solid land—if the place where we now stand was once a portion of the bottom of the ocean, over which its mighty billows for ages had rolled—if subterraneous fires have at different periods raised up from the bottom of the deep those huge mountains which now lift their summits to the clouds—if lofty mountains have been sunk down many thousand feet below their ancient level, so as to form deep valleys of the bottom of the seas—if the Almighty, after creating the matter of our globe, impressed certain laws upon its elementary substances, and left these laws to operate as they now do, with only occasional interferences—if races of animated beings have occupied the globe for myriads of ages—if new races have been created at different periods and subsequently destroyed—or if numerous orders of intelligent existence may have occupied the surface of the globe ages before man was introduced to this terrestrial scene—if tremendous convulsions have shaken the firm foundations of the earth—in short, if by all the processes to which we have alluded, our globe was gradually prepared for the purposes it now fulfills, and that the Creator chose to employ these rather than the special interposition of miraculous power—such considerations tend to exhibit the power, wisdom, and benevolence of the Deity, in a new point of view, and to enlarge our conceptions of the magnificent plans of him who is "The King eternal, immortal, and invisible," who is "wonderful in counsel and excellent in working." We are here shown that the space which has intervened between the present time and the period when man was first placed upon the globe, is but one of the units of a vast series of chronological periods which have gone before, and which stretch backward into the abyss of immeasurable duration. It is but a single link of the great chain which stretches from the moment when matter first arose from nothing, to diversify the wilds of immensity, down to the hour which is now passing over us. And who knows but that the system of the globe with which we are presently connected may be but one link in an interminable series of events connected with other orders of intelligences, which will be unfolded during the revolutions of a coming eternity.

The science of astronomy directs our views to regions of space which are immeasurable by mortals, and perhaps even by intelligences of a higher order, and discloses to our sight ten thousands and millions of magnificent orbs, whose existence was not even suspected 200 years ago. Geology directs our views to a stupendous series of events stretching back to the ages of a past eternity. The one conducts our vision to the far distant regions of immensity;—the other to the immeasurable periods of past duration; the one enlarges our conceptions of *space*, and the innumerable objects with which it is diversified;—the other expands our ideas of *time*, and the revolutions which have marked its progress. But astronomy has done more than this. Like Geology, it extends our views to periods of time immensely long in the flux of past duration—periods during which thousands of the luminaries of heaven have existed and displayed their radiance. Sir W. Herschel, in his remarks on the *Nebulæ*, has concluded, from a variety of ingenious reasonings and observations, that these nebulæ which assume a milky light or appearance, cannot be less than about 7000 times the distance of the star Sirius, or 168 thousand *billions* of miles; and from other observations, it is inferred that other bodies in the heavens are removed to a *much greater* distance. Now, light, notwithstanding its amazing velocity of 192,000 miles in a second, would be nearly *thirty thousand years* ere it could fly from such a nebulæ to the earth. Since, therefore, it is a fact that the light of such bodies has actually been seen, and consequently, that it must have been traveling at least many thousands of years before it could have reached the eyes of any of the inhabitants of our globe; it follows, that such bodies must have been brought into existence at far distant periods of past duration, otherwise they could not thus have darted their light through such vast spaces of immensity.

The discoveries of modern astronomy likewise disclose to us certain facts which lead us to the conclusion, that certain progressive operations are going forward, analogous to those which appear to have been carried forward in remote ages, in relation to our globe.—Had our limits permitted, we might have shown that some of the comets appear to be in an early stage of their progress toward becoming habitable worlds—that many of the nebulæ give evidence of a gradual progression toward condensation—that the appearance of new stars, the disappearance of others which had long shone in the heavens, and the gradual diminution of the light of others—the changes which appear to be occasionally taking place on the surfaces of the sun and the planets, along with other celestial phenomena—are indications that progression toward perfection, and perpetual change, are not peculiar to our world, but are principles in the Creator's government pervading the wide-extended universe.

In short, progressive improvement toward perfection forms a characteristic of the plans of the Almighty, not only in the physical, but also in the *moral* world. In the first instance, after the flood, the knowledge of the true God was chiefly confined to the family of Abraham; afterward, it was disseminated among the tribes of Israel, but circumscribed within the small territory of Judea; in process of time it was partially diffused among the surrounding nations; after the Christian era it spread abroad through the greater part of the Roman Empire; it has now extended its influence over most of the European nations, and over a certain portion of the tribes that inhabit Asia, Africa, and America. It is still in progress; and, on the foundation of the declarations of inspired prophets, we now look forward to the period when "the glory of Jehovah shall be revealed, and when all flesh shall see it together;" when "all the ends of the world shall remember and turn to the Lord," and "when righteousness and praise shall spring forth before all nations." And the scenes of a coming eternity will doubtless display changes and revolutions far surpassing in grandeur all the events which have happened during the myriads of ages which have already passed, and which will excite the astonishment and adoration of an admiring universe.—Even in an intellectual and political point of view, the nations are making progress toward perfection. "Old things are passing away," and new scenes of improvement are gradually unfolding. The state of society, in the island in which we dwell, 2000 years ago, presents nearly as great a contrast to what is now, as the chaotic state of our globe exhibited before it was reduced to the beauty and order in which we now behold it.—In short, everything we contemplate in the scene around us is progressive; the faculties of the human mind, and the corporeal powers from infancy to manhood—the growth of all the animal and vegetable races—the improvements of art, and the discoveries of science—education, civilization, and political economy—the cultivation of the earth, the mode of traveling by sea and land, and hundreds of other objects and movements demonstrate that *progression* is a law which pervades both the intellectual and the corporeal universe;—and, in the future world, the expansion of the human faculties, and the progress of the mind from one scene of material and intellectual grandeur to another, will form one portion of the happiness of renovated spirits: and as such a progression will never cease, their felicity will be of perpetual duration; for, if a finite spirit were to stop short in its excursions, or to arrive at a boundary where it could proceed no farther—from that moment its happiness would begin to diminish, and misery, to a certain extent, would infallibly ensue.

I have only to add, that whatever may be affirmed respecting the antiquity of the materials of which the earth is composed, it is admitted by every Geologist, that our globe, *as to its present state and arrangement*, has been comparatively of short duration. All the physical monuments which exist, and the progressive changes which have happened in the strata of the earth, as well as historical monuments, and the concurrent tradition of many nations, bear witness to this truth, that the first appearance of man upon the face of the globe cannot be referred to a period farther back than five or six thousand years from the present time.

Had the limits assigned to the present article permitted, I might have introduced some remarks on the 2d verse of the 1st chapter of Genesis, "The earth was without form and void," etc., or as it has sometimes been translated—"Afterward the earth became waste and desolate"—which expressions evidently imply that, at the period here alluded to, the substance or materials of the globe *did exist;* for we are told that the earth "*was*," or "*had become*," desolate or waste, previous to the arrangements which are subsequently described.

How long it had continued in this state, or in any of its previous states—whether a year, a century, or thousands of years, we are not informed, nor is there any expression in scripture which determines this, so that we are left at full liberty to carry our views on this point as far back into the ages of past duration as the facts connected with the structure of our globe may warrant, without controverting any position contained in the Sacred Oracles.—I might likewise have shown that the sun and stars must have been brought into existence *before* the period called the "fourth day," at which time they were appointed "to *rule* the day, and to be for signs and seasons, and for days and years"—and that the Creator, either through the medium of physical causes, or by a direct interposition of his power, produced the effects described in the Sacred Narrative—such as the separation of the ocean from the dry land—in the periods of time there specified. But the proof and illustration of such positions would occupy too much space in the present work.*

On the whole, the subject of Geology forms an interesting and instructive study both to the philosopher and to the Christian. When we take a survey of the august objects which diversify the surface of our globe; when we enter the wild and romantic scene of a mountainous country, or descend into the subterraneous regions of the globe, we are everywhere struck with the vestiges of operations carried on by the powers of Nature, upon a scale of prodigious magnitude, and with the exertion of forces, the stupendous nature of which astonishes and overpowers the mind? We seem as if standing on the ruins, and contemplating the vestiges of a former world. We behold

---

* For a further illustration of some of these topics, the author respectfully refers the reader to a Lecture, lately published, entitled "Discoveries of Modern Geology not inconsistent with Revelation"—being the 6th of a series of Lectures to Young Men, delivered in Broughton Place Church, Edinburgh, in March, 1842.

"hills" which "have melted like wax at the presence of the Lord," and "mountains" which "have been carried into the midst of the sea." We behold rocks of enormous size, which have been rent from their foundations, and rolled from one continent to another—the most solid strata of the earth bent under the action of some tremendous power, and dispersed in fragments throughout the surrounding regions. We behold the summits of lofty mountains, over which the ocean had rolled its mighty billows—confounding lands and seas in one universal devastation—transporting plants and forests from one quarter of the world to another, and spreading universal destruction among the inhabitants of the waters and the earth. Contemplating such scenes of grandeur, we perceive the force and sublimity of those descriptions of the Deity contained in the volume of inspiration. "The Lord reigneth; he is clothed with majesty; in his hand are the deep places of the earth, the strength of hills is his also. He removeth the mountains and they know not; he overturneth them in his anger; he shaketh the earth out of her place, and the pillars thereof tremble. At his presence the earth shook and trembled; the foundations also of the hills moved and were shaken. He covereth the earth with the deep as with a garment, the waters stood above the mountains. At his rebuke they fled; at the voice of his thunders they hastened away."

But, amidst all the revolutions and catastrophes that have taken place in the constitution of our globe, there is the clearest evidence of an All-wise and superintending Providence directing every event. Amidst the convulsions which have rent its strata—that have "carried hills into the midst of the seas"—and raised mountains from the bottom of the ocean—these are striking indications of Divine Benevolence in preparing our world for the comfort and accommodations its inhabitants now enjoy. The facts disclosed by geological investigation tend to enlarge our conceptions of the attributes of the Divinity, and of the sublimity of his plans and arrangements in the universe; and to demonstrate that his creating power has been repeatedly exercised during countless ages, in calling into existence numerous orders of beings, and in carrying forward his arrangements to a glorious consummation

ASTRONOMY.

Another science which stands in an intimate relation to religion, is Astronomy.

This sublime science teaches us the magnitudes and distances of the heavenly bodies, their arrangement, their various motions and phenomena, and the laws by which their movements are regulated. It presents to our view objects the most wonderful and sublime; whether we consider the *vast magnitude* of the bodies about which it is conversant—their immense *number*—the *velocity* of their motions—the *astonishing forces* requisite to impel them in their rapid career through the regions of the sky—the *vast spaces* which surround them, and in which they perform their revolutions—the *magnificent circles* they describe—the *splendor* of their appearance—or the *important ends* they are destined to serve in the grand system of the universe. Having adverted to this subject, when illustrating the Omnipotence of the Deity, I shall here simply state a few additional facts with respect to the general appearance of the heavens, the bodies which compose the planetary system, and the discoveries which have been made in the region of the stars.

When we lift our eyes toward the sky, we perceive an apparent hollow hemisphere, placed at an indefinite distance, and surrounding the earth on every hand. In the day-time, the principal object which appears in this hemisphere is the *sun*. In the morning, we see him rise above the distant mountains, or from the extremity of the ocean: he gradually ascends the vault of heaven, and then declines and disappears in the opposite quarter of the sky. In the northern parts of the globe, where we reside, if, about the 21st of March, we place ourselves on an open plain, with our face toward the south, the sun will appear to rise on our left, or due east, about six in the morning, and about the same hour in the evening he will set due west. In the month of June, he rises to our left, but somewhat behind us, in a direction toward the north-east, ascends to a greater hight at noon than in the month of March, and, after describing a large arc of the heavens, sets on our right and still behind us, in the north-western quarter of the sky. In the month of December, if we stand in the same position, we may observe, without turning ourselves, both his rising and setting. He rises in the south-east, ascends to a small elevation at noon, and sets in the south-west, after having described a very small arc of the heavens. Every day he appears to move a little toward the *east*, or contrary to his apparent diurnal motion; for the stars which are seen to the eastward of him, appear every succeeding day to make a nearer approach to the place in which he is seen. All the variety of these successive changes is accomplished within the period of 365 days 6 hours, in which time he appears to have made a complete revolution around the heavens from *west* to *east*.

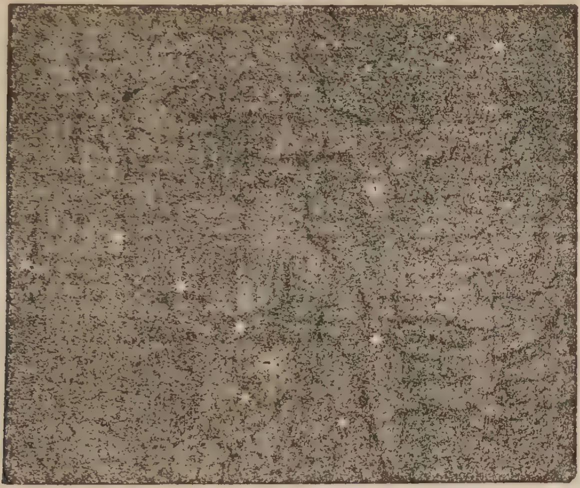
The *moon* is the next object in the heavens which naturally attracts our attention; and she is found to go through similar variations in the course of a month. When she first becomes visible at new moon, she appears in the western part of the heavens, in the form of a crescent, not far from the setting sun. Every night she increases in size, and removes to a greater distance from the sun, until at last she appears in the eastern part of the horizon, just as the sun disappears in the western; at which time she presents a round full-enlightened face. After this she gradually moves farther and farther eastward, and her enlightened part gradually decreases, until at last she seems to approach the sun as nearly in the east as she did in the west, and rises only a little before him in the morning, in the form of a crescent. All these different changes may be traced, by attending to her apparent positions, from time to time, with respect to the fixed stars.

A dark shadow is occasionally seen to move across the face of the moon, which obscures her light, and gives her the appearance of tarnished copper. Sometimes this shadow covers only a small portion of her surface; at other times it covers the whole of her disc for an hour or two, and its margin always appears of the figure of a segment of a circle. This phenomenon, which happens, at an average, about twice every year, is termed an *eclipse of the moon*. It is produced by the shadow of the earth falling upon the moon, when the sun, the earth, and the moon are nearly in a straight line; and can happen only at the time of *full moon*. Sometimes the moon appears to pass across the body of the sun; when her dark side is turned toward the earth, covering his disc either in whole or in part, and intercepting his rays from a certain portion of the earth. This is called an *eclipse of the sun*, and can happen only at the time of *new moon*. In a total eclipse of the sun, which seldom happens, the darkness is so striking, that some of the planets and sometimes the larger stars are seen, and the inferior animals appear struck with terror.

Again, if on a winter's evening, about six o'clock, we direct our view to the eastern quarter of the sky, we shall perceive certain stars just risen above the horizon; if we view the same stars about midnight, we shall find them at a considerable elevation in the south, having apparently moved over a space equal to one-half of the whole hemisphere. On the next morning, about six o'clock, the same stars will be seen setting in the western part of the sky. If we turn our eyes toward the north, we shall perceive a similar motion in these twinkling orbs; but with this difference, that a very considerable number of them neither rise nor set, but seem to move round an immovable point, called the north pole. Near this point is placed the pole star, which seems to have little or no apparent motion, and which, in our latitude, appears elevated a little more than half way between the northern part of our horizon and the *zenith*, or point above our heads.

The following cut, which represents the principal stars in the constellations *Ursa Major* and *Ursa Minor*, will enable the reader to recognize the Pole star, by attending to the following directions. The seven stars in the lower part of the figure represent Ursa Major, or the Great Bear, sometimes known by the names of the *Plow* and *Charles's Wain*. The stars on the upper part represent Ursa Minor, or the Little Bear, the largest star of which, on the right hand side, is the Pole star. About the beginning of November, at 6 or 7 o'clock in the evening, the Great Bear will appear near the north, at a low elevation above the horizon, and nearly in the position here represented. The two stars on the right hand side of the Great Bear are called the *Pointers*, and are distant from each other about 5 degrees. If a line connecting these stars be considered as prolonged upward to a considerable distance (about 29 degrees), until it meet the first bright star, that star is the *Pole star*, which is here represented at the higher part of the figure. Were the same observation made about the middle of April, at 10 o'clock in the evening, the Great Bear will appear almost directly over our heads, *above* the Pole star, and then we must conceive the line connecting the two Pointers as drawn *downward* toward the Pole star. At different times of the night, and at different periods of the year, the Great Bear will appear to be in different positions with respect to the Pole star, sometimes below, sometimes above, and at other times to the east or the west of it. But in all positions, a line drawn through the Pointers will always direct the eye to the Pole star.

Fig. 20.



A person who has directed his attention to the heavens for the first time, after having made such observations, will naturally inquire — Whence come those stars which begin to appear in the east? Whither have those gone which have disappeared in the west? and, What becomes, during the day, of the stars which are seen in the night?—It will soon occur to a rational observer, who is convinced of the roundness of the earth, that the stars which rise above the eastern horizon come from another hemisphere, which we are apt to imagine below us, and when they set, return to that hemisphere again; and that the reason why the stars are not seen in the day-time, is not because they are absent from our hemisphere, or have ceased to shine, but because their light is obscured by the more vivid splendor of the sun.[*]

---

[*] This is put beyond all doubt by the invention of the telescope; by which instrument, adapted to an equatorial motion, we are enabled to see many of the stars even at noonday. The author of this work, in 1812 and 1813, made a number of observations by means of an *Equatorial Telescope*, to determine the following particulars:—What stars and planets may be conveniently seen in the day-time, when the sun is above the horizon?—what degrees of magnifying power are requisite for distinguishing them?—how near their conjunction with the sun they may be seen?—and, whether the diminution of the aperture of the telescope, or the increase of magnifying power, conduces most to render a star or planet visible in day-light? The results of several hundreds of observations on these points, accompanied with some original deductions and remarks, are inserted in Nicholson's Philosophical Journal, for October 1813, vol. xxxvi, pp. 109–128. The following are some of the results which were deduced from the observations:—That a star of the *first* magnitude may be distinguished, at any time of the day, with a magnifying power of 30 times, but that a higher magnifying power is preferable—That most of the stars of the second magnitude may be seen with a power of 100; and with a power of 60 times, when the sun is not much more than two hours above the horizon—That the planet Jupiter,

From such observations we are led to conclude, that the globe on which we tread is suspended in empty space—is surrounded on all sides by the celestial vault—and that the whole sphere of the heavens has an *apparent* motion round the earth every twenty-four hours. Whether this motion be real, or only apparent, must be determined by other considerations.

Such general views of the nocturnal heavens, which every common observer may take, have a tendency to expand the mind, and to elevate it to the contemplation of an Invisible Power, by which such mighty movements are conducted. Whether we consider the vast concave, with all its radiant orbs, moving in majestic grandeur around our globe, or the earth itself whirling round its inhabitants in an opposite direction—an idea of sublimity, and of almighty energy, irresistibly forces itself upon the mind, which throws completely into the shade the mightiest efforts of human power. The most powerful mechanical engines that were ever constructed by the agency of man can scarcely afford us the least assistance in forming a conception of that incomprehensible Power, which, with unceasing energy, communicates motion to revolving worlds. And yet, such is the apathy with which the heavens are viewed by the greater part of mankind, that there are thousands who have occasionally gazed at the stars for the space of fifty years, who are still ignorant of the fact, that they perform an *apparent* diurnal revolution round our globe.

Again, if we contemplate the heavens with some attention, for a number of successive nights, we shall find, that by far the greater part of the stars never vary their positions with respect to each other. If we observe two stars at a certain apparent distance from each other, either north or south, or in any other direction, they will appear at the same distance, and in the same relative position to each other, the next evening, the next month, and the next year. The stars, for instance, which form the *sword* and *belt* of *Orion*, present to our eye the same figure and relative aspect, during the whole period they are visible in winter, and from one year to another; and the same is the case with all the fixed stars in the firmament. On examining the sky a little more minutely, however, we perceive certain bodies which regularly shift their positions. Sometimes they appear to move toward the east, sometimes toward the west, and at other times seem to remain in a stationary position. These bodies have obtained the name of *planets*, or wandering stars; and in our latitude are most frequently seen, either in the eastern and western, or in the southern parts of the heavens. Ten of these planetary orbs have been discovered: six of which are, for the most part, invisible to the naked eye. By a careful examination of the motions of these bodies, and their different aspects, astronomers have determined that they all move round the sun as the center of their motions, and form, along with the earth and several smaller globes, one grand and harmonious system. This assemblage of planetary bodies, is generally termed the Solar system, of which I shall now exhibit a brief outline.

THE SOLAR SYSTEM.

Of this system, the SUN is the center and the animating principle, and by far the largest body that exists within its limits. The first thing that strikes the mind when contemplating this glorious orb, is its astonishing magnitude. This vast globe is found to be about 880,000 miles in diameter, and consequently contains a mass of matter equal to *thirteen hundred thousand globes* of the size of the earth. Were its central parts placed adjacent to the surface of the earth, its circumference would reach two hundred thousand miles beyond the moon's orbit, on every side, filling a cubical space of 356,818,739,200,000,000 miles. If it would require 18,000 years to traverse every square mile on the earth's surface, at the rate of 30 miles a-day,* it would require more than *two hundred millions of years* to pass over every portion of the sun's surface, at the same rate. Even at the rate of 90 miles a-day, it would require more than 80 years to go round its circumference. Of a body so vast in its dimensions, the human mind, with all its efforts, can form no adequate conception. It appears an extensive universe in itself; and although no other body existed within the range of infinite space, this globe alone would afford a powerful demonstration of the Omnipotence of the Creator. Were the sun a hollow sphere, surrounded by an external shell and a luminous atmosphere; were this shell perforated with several hundreds of openings into the internal parts; were a globe as large as the earth placed at its center, and another globe as large as the moon, and at the same distance from the center as the moon is from us, to revolve round the central globe,—it would present to the view a universe as splendid and glorious as that which now appears to the vulgar eye—a universe as large and extensive as the whole creation was conceived to be by our ancestors, in the infancy of astronomy. And who can tell, but that the Almighty Being, who has not left a drop of water in a stagnant pool without its inhabitants, has arranged a number of worlds within the capacious circuit of the sun, and peopled them with intelligent beings in the first stages of their existence, to remain there for a certain period, until they be prepared for being transported to a more expansive sphere of existence? It is easy to conceive that enjoyments as exquisite, and a range of thought as ample, as have ever yet been experienced by the majority of the inhabitants of our world, might be afforded to myriads of beings thus placed at the center of this magnificent luminary. This supposition is

---

when not within 30 or 40 degrees of the sun, may be seen with a power of 15 times; and that Venus may, in most instances, be seen with a power of from 7 to 100 times, and upward—That Jupiter can scarcely be distinguished in the day-time, when within 26 degrees of the sun; but that Venus may be distinctly perceived near her superior conjunction, when only 1 degree and 27 minutes from the sun's margin: and consequently may be visible at the time of that conjunction, when her geocentric latitude equals or exceeds 1 degree 43 minutes—That she may be perceived like a fine slender crescent, within 35 hours after passing her *inferior* conjunction, etc. One practical purpose to which such observations on Venus, at the time of her *superior* conjunction, may be applied, is to determine the difference (if any) between her polar and equatorial diameters. For it is only at that conjunction that she presents to the earth a full enlightened hemisphere; and in no other position can the measure of both diameters be taken, except when she makes a *transit* across the sun's disc. As the earth, Mars, Jupiter, and Saturn, are found to be spheroids, it is highly probable that Venus is of a similar figure; but this point has never yet been ascertained by actual observation. See also the Edinburgh Philosophical Journal, No. V, for July 1820, p. 191; and No. XIII, for July 1822—The Scots' Magazine, for Feb. 1814, p. 84—Monthly Magazine, Feb. 1814, and August 1820, p. 62—Brewster's Ferguson's Astronomy, 2d edition, vol. ii, p. 111.—On March 10, 1842, the author saw Venus about 12 o'clock noon, when only 1° 21′ distant from the sun's eastern limb, with a 3½ feet achromatic telescope, magnifying 95 times—the aperture of the object glass being constructed to 1⅛ inches.

* See p. 18.

at least as probable as that of the celebrated Sir W. Herschel, who supposed that the *exterior* surface of the sun was peopled with inhabitants. For if this were the case, the range of view of these inhabitants would be confined within the limits of two or three hundred miles, and no celestial body, but an immense blaze of light would be visible in their hemisphere. Such is the variety which appears among the works of God, and such is the diversity of situations in which sensitive beings are placed, that we dare not pronounce it impossible that both these suppositions may be realized.

Though the sun seems to perform a daily circuit around our globe, he may be said, in this respect, to be fixed and immovable. This motion is not *real*, but only *apparent*, and is owing to the globe on which we are placed moving round its axis from west to east; just as the objects on the bank of a river seem to move in a contrary direction, when we are sailing along its stream in a steamboat. The only motion which is found to exist in the sun is a motion of *rotation*, like that of a globe or ball twirled round a pivot or axis, which is performed in the space of twenty-five days and ten hours. This motion has been ascertained by means of a variety of dark spots which are discovered by the telescope on the sun's disc; which first appear on his eastern limb, and after a period of about thirteen days, disappear on his western, and after a similar period reappear on his eastern edge. These spots are various, both in number, in magnitude, and in shape: sometimes forty or fifty, and sometimes only one or two, are visible, and at other times the sun appears entirely without spots. Most of them have a very dark nucleus, or central part, surrounded by an umbra, or fainter shade. Some of the spots are as large as would cover the whole continent of Europe, Asia, and Africa, others have been observed of the size of the whole surface of the earth; and one was seen, in the year 1779, which was computed to be more than *fifty thousand miles* in diameter.

With regard to the nature of this globe—it appears highly probable, from the observations of Sir W. Herschel, that the sun is a solid and opaque body, surrounded with luminous clouds which float in the solar atmosphere, and that the dark nucleus of the spots is the opaque body of the sun appearing through occasional openings in this atmosphere. The hight of the atmosphere he computes to be not less than 1843, nor more than 2755 miles, consisting of two regions; that nearest the sun being opaque, and probably resembling the clouds of our earth: the outermost emitting vast quantities of light, and forming the apparent luminous globe we behold.

The sun is the grand source of light and heat, both to the earth and to all the other planetary bodies. The heat he diffuses animates every part of our sublunary system, and all that variety of coloring which adorns the terrestrial landscape is produced by his rays. It has been lately discovered that the rays of light and the rays of heat, or *caloric*, are distinct from each other; for it can be demonstrated, that some rays from the sun produce heat, which have no power of communicating light or color. The greatest heat is found in the *red* rays, the least in the *violet* rays; and in a space beyond the red rays, where there is no light, the temperature is greatest. The rays of the sun have also been found to produce different chemical effects. The white muriate of silver is blackened in the violet ray in the space of fifteen seconds, though the red will not produce the same effect in less than twenty minutes. Phosphorus is kindled in the vicinity of the red ray, and extinguished in the vicinity of the violet. The solar light, therefore, consists of *three* different orders of rays, one producing *color*, a second producing *heat*, and a third *chemical* effects. Euler has computed that the light of the sun is equal to 6500 candles at a foot distance, while the moon would be as one candle at 7½ feet; Venus at 421 feet; and Jupiter at 1320 feet.—That this immense luminary appears so small to our eyes is owing to its vast distance, which is no less than ninety-five millions of miles. Some faint idea of this distance may be obtained, by considering that a steamboat, moving at the rate of 200 miles a-day, would require *thirteen hundred years* before it could traverse the space which intervenes between us and the sun.

> "Hail, sacred source of inexhausted light!
> Prodigious instance of creating might.
> His distance man's imagination foils;
> Numbers will scarce avail to count the miles.
> As swift as thought he darts his radiance round
> To distant worlds, his system's utmost bound."

The planet Mercury.—Mercury is the nearest planet to the sun that has yet been discovered.—He is about 37 millions of miles distant from the sun, and revolves around him in 88 days. His diameter is about 3200 miles. Before the discovery of the four new planets, Ceres, Pallas, Juno, and Vesta, in the beginning of the present century, this globe was considered as the smallest primary planet in the system. His surface, however, contains above 32 millions of square miles, which is not much less than all the habitable parts of our globe. On account of his nearness to the sun he is seldom seen by the naked eye; being always near that quarter of the heavens where the sun appears; and therefore few discoveries have been made on his surface by the telescope. M. Schroeter concludes, from certain observations, that this planet revolves round its axis in twenty-four hours and five minutes. The sun will appear to an inhabitant of Mercury seven times larger than to an inhabitant of the earth: and if the degree of heat be in proportion to a planet's nearness to the sun, the heat in this planet will be seven times greater than on the surface of our globe; and consequently, were the earth placed in the same position, all the water on its surface would boil, and soon be turned into vapor. But the All-wise Creator has doubtless attempered the surface of that globe, and the constitution of the beings that may occupy it, to the situation in which they are placed.*

Venus, the next planet in order from the sun, revolves around him in 224 days, at the distance of 68 millions of miles: its diameter is about seven thousand seven hundred miles, or nearly the size of the earth; and it turns round its axis in the space of 23 hours and 20 minutes. This planet is the most brilliant orb which appears in our nocturnal heavens, and is usually distinguished by the name of the morning and evening star.—When it approaches nearest to the earth, it is about 27 millions of miles distant; and, at its greatest distance, it is no less than 163 millions of miles from the earth. Were the whole of its enlightened surface turned toward the earth when it is nearest, it would exhibit a light and brilliancy twenty-five times greater than it generally does, and appear like a small brilliant moon; but at that time its dark hemisphere is turned toward our globe. Both Venus and Mercury, when viewed by a telescope, appear to pass successively through all the shapes and appearances of the moon; sometimes assuming a gibbous phase, and at other times the form of a half moon, or that of a crescent; which proves that they are dark bodies in themselves, and derive their light from the sun. The most distinct and beautiful views of Venus, especially when it appears as a crescent, are to be obtained in *the day-time*, by means of an equatorial telescope.—From a variety of observations which the author has made with this instrument, it has been found that Venus may be seen every clear day, without interruption, during a period of 583 days, with the occasional exception of thirteen days in one case and only three days in another—circumstances which cannot be affirmed of any other celestial body, the sun only excepted.* M. Schroeter affirms that he has discovered mountains on the surface of this globe, one of which is 10, another 11, and a third 22 miles high. It appears also to be encompassed with an atmosphere, the densest part of which is about 16,000 feet high. About twice in the course of a century this planet appears to pass, like a dark spot, across the sun's disc. This is termed the *transit* of Venus. The last transit happened June 3, 1769; the next will happen on December 8, 1874, which will be invisible in Europe. Another will happen on the 6th December, 1882, which will be partly visible in Great Britain.

---

* From a variety of facts which have been observed in relation to the production of *Caloric*, it does not appear probable that the degree of heat on the surfaces of the different planets is inversely proportional to the squares of their respective distances from the sun. It is more probable that it depends chiefly on the distribution of the *substance of caloric* on the surfaces and throughout the atmospheres of these bodies—in different quantities, according to the different situations they occupy in the Solar system; and that these different quantities of caloric are put into action by the influence of the solar rays, so as to produce that degree of *sensible* heat requisite for each respective planetary globe. On this hypothesis—which is corroborated by a great variety of facts and experiments—there may be no more sensible heat felt on the surface of the planet Mercury than on the surface of Uranus, although one of these bodies is nearly 50 times nearer the sun than the other. We have only to suppose that a small quantity of caloric exists in Mercury and a larger quantity in Uranus, proportionate to the distance from the center of the system. On this ground, we have no reason to believe either that the planets nearest the sun are parched with excessive heat, or that those that are most distant are exposed to all the rigors of insufferable cold, or that the different degrees of temperature which may be found in these bodies render them unfit for being the abodes of sensitive and intellectual beings.

The EARTH is the next planet in the system.—It moves round the sun in 365 days 5 hours and 49 minutes, at the distance of 95 millions of miles, and round its axis in 23 hours 56 minutes 4 seconds. The former is called its *annual*, and the latter its *diurnal* motion. That the earth is, in reality, a moving body, is a fact which can no longer be called in question; it is indeed susceptible of the clearest demonstration. But my limits will not permit to enter into a detail of the arguments by which it is supported. I have already adverted to one consideration, from which its diurnal rotation may be inferred.* Either the earth moves round its axis every day, or *the whole universe* moves round it in the same time. To suppose the latter case to be the fact would involve a reflection on the wisdom of its Almighty Author, and would form the only exception that we know to that beautiful proportion, harmony, and simplicity, which appear in all the works of Nature. Were it possible to construct a machine as large as the city of London, and apply to it mechanical powers sufficient to make it revolve on an axis, so as to carry round a furnace for the purpose of roasting a joint of mutton, suspended in the center of its motion—while we might admire the ingenuity and the energies displayed in its construction—all mankind would unite in condemning it as a display of consummate folly. But such an extravagant piece of machinery would not be half so preposterous as to suppose, that the vast universe is daily revolving around our little globe, and that all the planetary motions have an immediate respect to it. And shall we dare ascribe to Him who is "the only wise God," contrivances which we would pronounce to be the perfection of folly in mankind? It is recorded of the astronomer Alphonsus, king of Castile, who lived in the 13th century, that, after having studied the Ptolemaic system, which supposes the earth at rest in the center of the universe, he uttered the following *impious* sentence: "If I had been of God's privy council when he made the world, I would have advised him better." So that false conceptions of the System of Nature lead to erroneous notions of that adorable Being who is possessed of Infinite Perfection.—We find that bodies much larger than the earth have a similar rotation. The planet Jupiter, a globe 295,000 miles in circumference, moves round its axis in less than ten hours; and all the other planetary bodies, on which spots have been discovered, are found to have a diurnal motion. Beside, it is found to be a universal law of nature, that smaller globes revolve around larger; but there is no example in the universe, of a larger body revolving around a smaller. The moon revolves around the earth, but she is much smaller than the earth; the moons which move around Jupiter, Saturn, and Herschel, are all less than their primaries, and the planets which perform their revolutions around the sun are much less than that central luminary.

With regard to the *annual* revolution of the earth,—if such a motion did not exist, the planetary system would present a scene of inextricable confusion. The planets would sometimes move backward, sometimes forward, and at other times remain stationary; and would describe looped curves, so anomalous and confused, that no man in his senses could view the All-wise Creator as the author of so much confusion. But, by considering the earth as revolving in an orbit between Venus and Mars (which all celestial observations completely demonstrate), all the apparent irregularities of the planetary motions are completely solved and accounted for; and the Solar System presents a scene of beauty, harmony, and grandeur, combined with a simplicity of design, which characterizes all the works of Omnipotence.

---

* See Edin. Phil. Journ., No. V, July 1820, and No. XIII. July 1822.—I have found from observation that this planet may be seen in the day-time, when only 1° 21′ from the sun's center; and consequently, when its geocentric latitude at the time of the superior conjunction exceeds that quantity, it may be distinctly seen during the whole period of 583 days, excepting about 25 hours before and after its *inferior* conjunction.—It is well known to astronomers that there has been a difference of opinion with respect to the *period* of the rotation of this planet. Cassini, from observations on a bright spot which advanced 20 degrees in 24 hours 34 minutes, determined the time of its rotation to be 23 hours and 20 minutes. On the other hand, Bianchini, from similar observavations, concluded that its diurnal period was 24 days and 8 hours. The difficulty of deciding between these two opinions arises from the short time in which observations can be made in this planet, either before sunrise or after sunset, which prevents us from tracing with accuracy the progressive motion of its spots for a sufficient length of time. And although an observer should mark the position of the spots, at the same hour, on two succeeding evenings, and find they had moved forward about 20 degrees in 24 hours, he would still be at a loss to determine whether they had moved 20 degrees *in all*, since the preceding observation, or had finished a revolution, and 20 degrees more.—In Nicholson's Philosophical Journal, vol. xxxvi. I endeavored to show how this point may be determined by observations made on Venus in the day-time, by which, in certain cases, the progressive motion of its spots might be traced, without interruption for 12 hours or more, which would completely settle the period of rotation.

* See p. 22.

The MOON.—Next to the sun, the moon is to us the most interesting of all the celestial orbs.—She is the constant attendant of the earth, and revolves around it in 27 days 8 hours; but the period from one new or full moon to another, is about 29 days 12 hours. She is the nearest of all the heavenly bodies; being only about two hundred and forty thousand miles distant from the earth. She is much smaller than the earth; being only 2180 miles in diameter. Her surface, when viewed with a telescope, presents an interesting and a variegated aspect; being diversified with mountains, valleys, rocks, and plains, in every variety of form and position. Some of these mountains form long and elevated ridges, resembling the chains of the Alps and the Andes; while others, of a conical form, rise to a great hight, from the middle of level plains, somewhat resembling the Peak of Teneriffe. But the most singular feature of the moon is, those circular ridges and cavities which diversify every portion of her surface. A range of mountains of a circular form, rising three or four miles above the level of the adjacent districts, surrounds, like a mighty rampart, an extensive plain; and, in the middle of this plain or cavity, an insulated conical hill rises to a considerable elevation. Several hundreds of these circular plains, most of which are considerably below the level of the surrounding country, may be perceived with a good telescope, on every region of the lunar surface. They are of all dimensions, from two or three miles to forty miles in diameter; and, if they be adorned with verdure, they must present to the view of a spectator, placed among them, a more variegated, romantic, and sublime scenery than is to be found on the surface of our globe. An idea of some of these scenes may be acquired, by conceiving a plain of about a hundred miles in circumference, encircled with a range of mountains, of various forms, three miles in perpendicular hight, and having a mountain near the center, whose top reaches a mile and a half above the level of the plain. From the top of this central mountain, the whole plain, with all its variety of objects, would be distinctly visible; and the view would appear to be bounded on all sides by a lofty amphitheater of mountains, in every diversity of shape, rearing their summits to the sky. From the summit of the circular ridge, the conical hill in the center, the opposite circular range, the plain below, and some of the adjacent plains, which encompass the *exterior* ridge of the mountains, would form another variety of view;—and a third variety would be obtained from the various aspects of the central mountain, and the surrounding scenery as viewed from the plains below.

The lunar mountains are of all sizes, from a furlong to five miles in perpendicular elevation. Certain luminous spots, which have been occasionally seen on the dark side of the moon, seem to demonstrate that fire exists in this planet. Sir W. Herschel, and several other astronomers, suppose that they are volcanoes in a state of eruption. It would be a more pleasing idea, and perhaps as nearly corresponding to fact, to suppose, that these phenomena are owing to some occasional splendid illuminations produced by the lunar inhabitants, during their long nights. Such a scene as the burning of Moscow, the conflagration of an extensive forest, or the splendid illumination of a large city with gas-light, might present similar appearances to a spectator in the moon.—The bright spots on the moon are the mountainous regions: the dark spots are the plains, or more level parts of the surface. There may probably be rivers or small lakes on this planet; but there are no seas or large collections of water. It appears highly probable, from the observations of Schroeter, that the moon is encompassed with an atmosphere: but no clouds, rain, or snow, seem to exist in it. The illuminating power of the light derived from the moon, according to the experiments made by professor Leslie, is about the *one hundred and fifty thousandth part* of the illuminating power of the sun. According to the experiments of M. Bouguer, it is only as 1 to 300,000.

The moon always presents the same face to us, which proves, that she revolves round her axis in the same time that she revolves round the earth. As this orb derives its light from the sun, and reflects a portion of it upon the earth, so the earth performs the same office to the moon. A spectator on the lunar surface would behold the earth like a luminous orb suspended in the vault of heaven, presenting a surface about 13 times larger than the moon does to us, and appearing sometimes gibbous, sometimes horned, and at other times with a round full face. The light which the earth reflects upon the dark side of the moon may be distinctly perceived by a common telescope, from two to six or eight days after the change.—The lunar surface contains about 15 millions of square miles, and is, therefore, capable of containing a population equal to that of our globe, allowing only about 53 inhabitants to every square mile. That this planet is inhabited by sensitive and intelligent beings, there is every reason to conclude, from a consideration of the sublime scenery with which its surface is adorned, and of the general beneficence of the Creator, who appears to have left no large portion of his material creation without animated existences; and it is highly probable, that *direct proofs* of the moon's being inhabited may hereafter be obtained, when all the varieties on her surface shall have been more minutely explored.*

The planet MARS.—Next to the earth and moon, the planet Mars performs his revolution round the sun, in one year and ten months, at the distance of 145 millions of miles. His diameter is about 4200 miles, and he is distinguished from all the other planets by his *ruddy* appearance, which is owing to a *dense atmosphere* with which he is environed. With a good telescope, his surface appears diversified with a variety of spots; by the motion of which it is found, that he turns round his axis in 24 hours and 40 minutes. The inclination of his axis to the plane of his orbit being about 28° 42′, the days and nights, and the different seasons in this planet, will bear a considerable resemblance to those we experience in our terrestrial sphere.† At his nearest approach to the earth, his distance from us is about 50 millions of miles; and, at his greatest distance, he is about 240 millions of miles; so that in the former case he appears nearly 25 times larger than in the latter. To a spectator in this planet, our earth will appear alternately, as a morning and evening star, and will exhibit all the phases of the moon, just as Venus does to us, but with a less degree of apparent magnitude and splendor. A luminous zone has been observed about the poles of Mars, which is subject to successive changes. Sir W. Herschel supposes that it is produced by the reflection of the sun's light from his frozen regions, and that the melting of these masses of polar ice is the cause of the variation in its magnitude and appearance. This planet moves, in its orbit, at the rate of fifty-five thousand miles an hour.

---

* See Appendix, Note IV.

† The inclination of the earth's axis to the ecliptic, or, in other words, to the plane of its annual orbit is 23° 28′, which is the cause of the diversity of seasons, and of the different length of days and nights. Were the axis of the earth perpendicular to its orbit, as is the case with the planet Jupiter, there would be no diversity of seasons.

The NEW PLANETS.—Between the orbits of Mars and Jupiter, four planetary bodies have been lately discovered, accompanied with circumstances somewhat different from those of the other bodies which compose our system. They are named *Ceres, Pallas, Juno, Vesta*. The planet *Ceres* was discovered at Palermo, in Sicily, by M. Piazzi, on the first day of the present century. It is of a ruddy color, and appears about the size of a star of the eighth magnitude, and is consequently invisible to the naked eye. It performs its revolution in 4 years and 7 months, at the distance of 260 millions of miles from the sun, and is reckoned by some astronomers to be about 1624 miles in diameter, or about half the diameter of Mercury. It appears to be surrounded with a large dense atmosphere.—Pallas was discovered the following year, namely, on the 28th March, 1802, by Dr. Olbers, of Bremen. It is supposed to be about 2000 miles in diameter, or nearly the size of the moon. It revolves about the sun in 4 years and 7 months, or nearly in the same time as Ceres, at the distance of 266 millions of miles; and is surrounded with a nebulosity or atmosphere above 400 miles in hight, similar to that of Ceres.—The planet *Juno* was discovered on the 1st September, 1804, by Mr. Harding, of Bremen. Its mean distance from the sun is about 253 millions of miles; its revolution is completed in 4 years and 130 days, and its diameter is computed to be about 1425 miles. It is free from the nebulosity which surrounds Pallas, and is distinguished from all the other planets by the great eccentricity of its orbit; being at its least distance from the sun only 189 millions of miles, and at its greatest distance, 316 millions.—*Vesta* was discovered by Dr. Olbers on the 29th March, 1807. It appears like a star of the fifth or sixth magnitude, and may sometimes be distinguished by the naked eye. Its light is more intense and white than any of the other three, and it is not surrounded with any nebulosity. It is distant from the sun about 225 millions of miles, and completes its revolutions in 3 years and 240 days. Its diameter has not yet been accurately ascertained; but from the intensity of its light and other circumstances, it is concluded, that it is not inferior in magnitude to either Pallas or Juno.

These planetary globes present to our view a variety of anomalies and singularities, which appear incompatible with the regularity, proportion, and harmony, which were formerly supposed to characterize the arrangements of the Solar system.—They are bodies *much smaller* in size than the other planets—they revolve *nearly at the same distances* from the sun, and perform their revolutions in *nearly the same periods*—their orbits are *much more eccentric*, and have a *much greater degree of inclination* to the ecliptic, than those of the old planets—and, what is altogether singular (except in the case of comets), *their orbits cross each other;* so that there is a *possibility* that two of these bodies might happen to interfere, and to strike each other, in the course of their revolutions. The orbit of Ceres crosses the orbit of Pallas. Vesta may sometimes be at a greater distance from the sun than either Ceres, Pallas, or Juno, although its mean distance is less than that of either of them, by several millions of miles; so that the orbit of Vesta crosses the orbits of all the other three. From these and other circumstances, it has, with a high degree of probability been concluded—that these four planets are the fragments of a large celestial body which once revolved between Mars and Jupiter, and which had been burst asunder by some immense irruptive force. This idea seems to have occurred to Dr Olbers, after he had discovered the planet Pallas, and he imagined that other fragments might possibly exist. He concluded, that, if they all diverged from the same point, "they ought to have two common points of reunion, or two nodes in opposite regions of the heavens, through which all the planetary fragments must sooner or later pass." One of these nodes he found to be in the constellation Virgo, and the other in the Whale; and it is a remarkable coincidence, that it was in the latter of these regions that the planet Juno was discovered by Mr. Harding. In order to detect the remaining fragments (if any existed), Dr. Olbers examined, three times every year, all the small stars in Virgo and the Whale; and it was actually in the constellation Virgo that he discovered the planet Vesta. It is not unlikely that other fragments of a similar description may yet be discovered. Sir D. Brewster attributes the fall of meteoric stones* to the smaller fragments of these bodies happening to come within the sphere of the earth's attraction. His ingenious reasoning on this subject, and in support of Dr Olbers' hypothesis above stated, may be seen in *Edin. Encyc.*, vol. ii, p. 641, and in his "supplementary chapters to Ferguson's Astronomy."

The facts to which I have now adverted seem to unfold a new scene in the history of the dispensations of the Almighty, and to warrant the conclusion, that the earth is not the only globe in the universe which is subject to physical changes and moral revolutions.

The Planet JUPITER.—This planet is 490 millions of miles distant from the sun, and performs its annual revolution in nearly twelve of our years, moving at the rate of twenty-nine thousand miles an hour. It is the largest planet in the Solar system, being 89,000 miles in diameter, or about *fourteen hundred times* larger than the earth. Its motion round its axis is performed in nine hours and fifty-six minutes; and, therefore, the portions of its surface about the equator, move at the rate of 28,000 miles an hour, which is nearly twenty-seven times swifter than the earth's diurnal rotation. The figure of Jupiter is that of an oblate spheroid, the axis, or diameter, passing through the poles, being about 6000 miles shorter than that passing through the equator. The Earth, Saturn, and Mars, are also spheroids; and it is highly probable that Mercury, Venus, and Herschel, are of a similar figure, though the fact has not yet been ascertained by actual observation. When viewed with a telescope, several spots have been occasionally discovered on the surface of this planet, by the motion of which its rotation was determined.

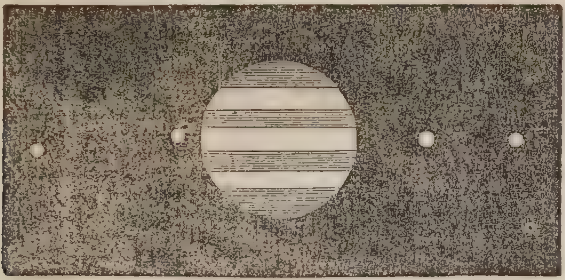
---

* Meteoric stones, or what are generally termed *aerolites*, are stones which sometimes fall from the upper regions of the atmosphere upon the earth. The substance of which they are composed is, for the most part, *metallic;* but the ore of which they consist is not to be found *in the same constituent proportions*, in any terrestrial substances. Their fall is generally preceded by a luminous appearance, a hissing noise, and a loud explosion; and, when found immediately after their descent, are always hot. Their size differs from small fragments of inconsiderable weight, to the most ponderous masses. Some of the larger portions of these stones have been found to weigh from 300 lbs. to several tons; and they have often descended to the earth with a force sufficient to bury them several feet under the soil. Some have supposed that these bodies are projected from volcanoes in the moon; others, that they proceed from volcanoes on the earth; while others imagine that they are generated in the regions of the atmosphere; but the true cause is probably not yet ascertained. In some instances these stones have penetrated through the roofs of houses, and proved destructive to the inhabitants.

But what chiefly distinguishes the surface of Jupiter, is several streaky appearances, or dusky stripes, which extend across his disc in lines parallel to his equator. These are generally termed his *Belts*. Three of these belts, or zones, nearly equi-distant from each other, are most frequently observed; but they are not regular or constant in their appearance.* Sometimes only one is to be seen, sometimes five, and sometimes seven or eight have been visible; and in the latter case, two of them have been known to disappear during the time of observation. On the 28th of May, 1780, Sir W. Herschel perceived "the *whole surface of Jupiter* covered with small curved belts, or rather lines, that were not continuous across his disc." Though these belts are generally parallel to each other, yet they are not always so. Their breadth is likewise variable; one belt having been observed to grow narrow, while another in its neighborhood has increased in breadth, as if the one had flowed into the other. The time of their continuance is also uncertain; sometimes they remain unchanged for several months, at other times, new belts have been formed in an hour or two. What these belts, or variable appearances are, it is difficult to determine. Some have regarded them as strata of clouds floating in the atmosphere of Jupiter; while others imagine, that they are the marks of great physical revolutions which are perpetually changing the surface of that planet. The former opinion appears the most probable. But whatever be the nature of these belts, the sudden changes to which they are occasionally subject, seem to indicate the rapid operation of some powerful physical agency; for some of them are more than five thousand miles in breadth; and since they have been known to disappear in the space of an hour or two, or even during the time of a casual observation—agents more powerful than any with which we are acquainted must have produced so extensive an effect.

Jupiter is attended by four satellites, or moons, which present a very beautiful appearance when viewed through a telescope. The first moon, or that nearest the planet, is 230,000 miles distant from its center, and goes round it in 42½ hours; and will appear from its surface four times larger than our moon does to us. The second moon, being farther distant, will appear about the size of ours; the third, somewhat less; and the fourth which is a million of miles distant from Jupiter, and takes sixteen days to go round him, will appear only about one-third the diameter of our moon. These moons suffer frequent eclipses from passing through Jupiter's shadow, in the same way as our moon is eclipsed by passing through the shadow of the earth. By the eclipses of these moons, the motion of light was ascertained; and they are found to be of essential use, in determining the longitude of places on the surface of our globe. This planet, if seen from its nearest moon, will present a surface a thousand times as large as our moon does to us, and will appear in the form of a crescent, a half moon, a gibbous phase, and a full moon, in regular succession every 42 hours.

Fig. 21.



The foregoing figure exhibits a view of Jupiter's belts and satellites as seen through a good telescope; but they do not always appear, two on each side, as here represented, but in every variety of position; and sometimes all on the same side, in the order of their distances; and they seem to move from one side to another, in nearly straight lines, on account of our eye being nearly on a level with the planes of their orbits.

Jupiter's axis being nearly perpendicular to his orbit, he has no sensible change of seasons, such as we experience on the earth. Were we placed on the surface of this planet, with the limited powers of vision we now possess, our earth and moon would entirely disappear, as if they were blotted out from the map of creation; and the inhabitants of these regions must have much better eyes than ours, if they know that there is in the universe such a globe as the earth.

The Planet Saturn.—This planet is 900 millions of miles distant from the sun, being nearly double the distance of Jupiter. Its diameter is 79,000 miles, and consequently, it is more than *nine hundred times* the bulk of the earth. It takes it 29½ years to complete its revolution about the sun; but its diurnal motion is completed in ten hours and sixteen minutes; so that the year in this planet is nearly thirty times the length of ours, while the day is shorter, by more than one-half. The year, therefore, contains about twenty-five thousand one hundred and fifty *days*, or periods of its diurnal rotation, which is equal to 10,759 of our days. Saturn is of a spheroidal figure, or somewhat of the shape of an orange; his equatorial being more than six thousand miles longer than his polar diameter. His surface, like that of Jupiter, is diversified with belts and dark spots. Sir W. Herschel, at certain times, perceived five belts on his surface, three of which were dark, and two bright. The dark belts had a yellowish tinge, and generally covered a larger zone of the disc of Saturn than the belts of Jupiter occupy upon his surface. On account of the great distance of this planet from the sun, the light it receives from that luminary is only the *ninetieth part* of what we enjoy; but, by calculation, it is found that this quantity is a thousand times greater than the light which the full moon affords to us. Beside, it is surrounded by no fewer than seven moons, which supply it with light in the absence of the sun. Five of these moons were discovered during the seventeenth century, by Huygens and Cassini; and the sixth and seventh were discovered by Sir W. Herschel, in 1789, soon after his large forty feet reflecting telescope was constructed. These moons, and also those which accompany Jupiter, are estimated to be not much less than the earth in magnitude, and are found, like our moon, to revolve round their axes in the same time in which they revolve about their respective primaries.

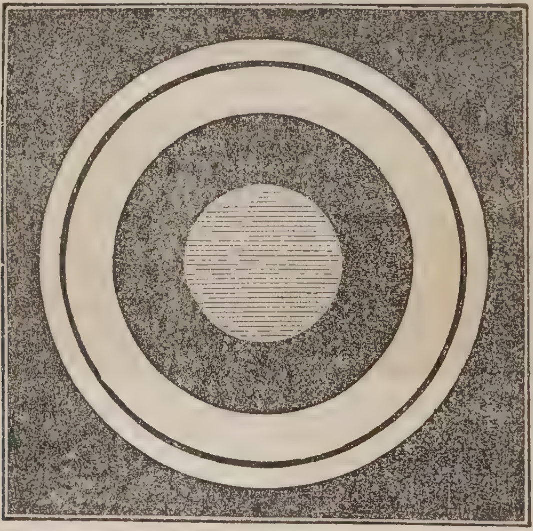
---

* A representation of these belts in the positions in which they most frequently appear, is exhibited in the Frontispiece, Fig. 2.—Fig. 1 represents the double ring of Saturn as it appears when viewed through a powerful telescope.—Figures 1, 2, 3, 4, etc., represent Saturn, Jupiter, Herschel, the earth, and moon, *in their relative sizes and proportions.*

Rings of Saturn.—The most extraordinary circumstance connected with this planet is, the phenomenon of a *double ring*, which surrounds its body, but nowhere touches it, being thirty thousand miles distant from any part of the planet, and is carried along with the planet in its circuit around the sun. This is the most singular and astonishing object in the whole range of the planetary system; no other planet being found environed with so wonderful an appendage: and the planets which may belong to other systems, being placed beyond the reach of our observations, no idea can be formed of the peculiar apparatus with which any of them may be furnished. This double ring consists of two concentric rings, detached from each other; the innermost of which is nearly three times as broad as the outermost The outside diameter of the *exterior* ring is 204,000 miles; and consequently, in circumference, will measure *six hundred and forty thousand miles*, or eighty times the diameter of our globe. Its breadth is 7200 miles, or nearly the diameter of the earth. Were four hundred and fifty globes, of the size of the earth, placed close to one another, on a plane, this immense ring would inclose the whole of them, together with all the interstices, or open spaces between the different globes. The outside diameter of the *innermost* ring is 184,000 miles, and its breadth 20,000 miles, or about 2½ times broader than the diameter of the earth. The dark space, or interval between the two rings, is 2800 miles. The breadth of both the rings, including the dark space between them, is thirty thousand miles, which is equal to the distance of the innermost ring from the body of Saturn.

The following figure represents a view of Saturn and his rings, as they would appear were our eye perpendicular to one of the planes of those rings; but our eye is never so much elevated above either plane as to have the visual ray standing at right angles to it: it is never elevated more than 30 degrees above the planes of the rings When we view Saturn through a telescope, we always see the ring at an oblique angle, so that it appears of an *oval* form, the outward circular ring being projected into an ellipsis more or less oblong, according to the different degrees of obliquity with which it is viewed, as will be seen in the Frontispiece.

Fig. 22.



These rings cast a deep shadow upon the planet, which proves that they are not shining *fluids*, but composed of *solid* matter. They appear to be possessed of a higher reflective power than the surface of Saturn: as the light reflected by them is more brilliant than that of the planet. One obvious use of this double ring is, to reflect light upon the planet in the absence of the sun in all probability, it also serves as an ample habitation for myriads of sensitive and intelligent beings; for the surfaces of the two rings contain no less than 228 millions of square miles, or about 600 times more than all the habitable parts of our globe, and it is not likely that, in the wise arrangements of the Creator, such an immense space would be left destitute of inhabitants: what other purposes it may be intended to subserve, in the system of Saturn, is at present to us unknown. The sun illuminates one side of it during fifteen years, or one half of the period of the planet's revolution; and, during the next fifteen years, the other side is enlightened in its turn. Twice in the course of thirty years, there is a short period, during which neither side is enlightened, and when, of course, it ceases to be visible;—namely, at the time when the sun ceases to shine on one side, and is about to shine on the other. It revolves round its axis, and consequently around Saturn, in ten hours and a half, which is at the rate of a thousand miles in a minute, or fifty-eight times swifter than the earth's equator. When viewed from the middle zone of the planet, in the absence of the sun, the rings will appear like vast luminous arches, extending along the canopy of heaven, from the eastern to the western horizon; having an apparent breadth equal to a hundred times the apparent diameter of our moon, and will be seen darkened about the middle, by the shadow of Saturn.[*]

There is no other planet in the Solar system, whose firmament will present such a variety of splendid and magnificent objects, as that of Saturn. The various aspects of his seven moons, one rising above the horizon, while another is setting, and a third approaching to the meridian; one entering into an eclipse, and another emerging from it; one appearing as a crescent, and another with a gibbous phase; and sometimes the whole of them shining in the same hemisphere, in one bright assemblage;—the majestic motions of the rings,—at one time illuminating the sky with their splendor, and eclipsing the stars; at another, casting a deep shade over certain regions of the planet, and unvailing to view the wonders of the starry firmament—are scenes worthy of the majesty of the Divine Being to unfold, and of rational creatures to contemplate. Such magnificent displays of Wisdom and Omnipotence, lead us to conclude that the numerous splendid objects connected with this planet, were not created merely to shed their luster on naked rocks and barren sands; but that an immense population of intelligent beings is placed in those regions, to enjoy the bounty and to adore the perfections of their great Creator.

The double ring of Saturn, when viewed through a good telescope, generally appears like a luminous handle on each side of the planet, with a dark interval between the interior edge of the ring, and the convex body of Saturn; which is owing to its oblique position with respect to our line of vision. When its outer edge is turned directly toward the earth, it becomes invisible, or appears like a dark stripe across the disc of the planet as it did in 1832. This phenomenon happens once every fifteen years.

The Planet Herschel.—This planet, which is also known by the names of the *Georgium Sidus*, and *Uranus*, was discovered by Sir W. Herschel on the 13th of March, 1781. It is the most distant planet from the sun that has yet been discovered; being removed at no less than 1800 millions of miles from that luminary, which is nineteen times farther than the earth is from the sun—a distance so great, that a cannon ball, flying at the rate of 480 miles an hour, would not reach it in 400 years. Its diameter is about 35,000 miles; and of course, it is about eighty times larger than the earth. It appears like a star of the sixth magnitude; but can seldom be distinguished by the naked eye. It takes about 83 years and a half to complete its revolution round the sun; and, though it is the slowest moving body in the system, it moves at the rate of 15,000 miles an hour. As the degree of sensible heat in any planet does not appear to depend altogether on its nearness to the sun, the temperature of this planet may be as mild as that which obtains in the most genial climate of our globe.[*] The diameter of the sun, as seen from Herschel, is little more than the apparent diameter of Venus as seen by the naked eye; and the light which it receives from that luminary, is 360 times less than what we experience; yet this proportion is found by calculation to be equal to the effect which would be produced by 248 of our full moons; and, in the absence of the sun, there are *six moons* which reflect light upon this distant planet, all of which were discovered likewise by Sir W. Herschel. Small as the proportion of light is which this planet receives from the sun, it is easy to conceive, that beings similar to man, placed on the surface of this globe, with a slight modification of their organs of vision, might be made to perceive objects with a clearness and distinctness even superior to what we can do. We have only to suppose, that the Creator has formed their eyes with *pupils* capable of a much larger expansion than ours; and has indued their *retina* with a much greater degree of nervous sensibility. At all events, we may rest assured, that He who has placed sentient beings in any region, has, by laws with which we are partly unacquainted, adapted the constitution of the inhabitant to the nature of the habitation.

> "Strange and amazing must the difference be
> 'Twixt this dull planet and *bright Mercury!*
> Yet reason says, nor can we doubt at all,
> Millions of beings dwell on either ball,
> With constitutions fitted for that spot
> Where Providence, all-wise, has fixed their lot."

The celestial globes which I have now described, are all the planets which are at present known to belong to the Solar system. It is probable that other planetary bodies may yet be discovered between the orbits of Saturn and Herschel, and even far beyond the orbit of the latter; and it is also not improbable, that planets may exist in the immense interval of 37 millions of miles between Mercury and the Sun.[†] These (if any exist) can be detected only by a series of *day observations*, made with equatorial telescopes; as they could not be supposed to be seen, after sunset, on account of their proximity to the sun. Five *primary*[‡] planets, and eight *secondaries*, have been discovered within the last 60 years; and, therefore, we have no reason to conclude, that all the bodies belonging to our system have yet been detected, until every region of the heavens be more fully explored.

---

[*] See the Frontispiece, Fig 7, which represents a view of the appearance which the rings and moons of Saturn will exhibit, in certain cases, about midnight, when beheld from a point 20 or 30 degrees north from his equator. The shade on the upper part of the rings represents the shadow of the body of Saturn. This shadow will appear to move gradually to the west as the morning approaches.—From observations which were made some time ago by Captain Kater, Professor Quetelet, and others, it has been surmised that the *outer* ring of Saturn is divided into several smaller rings. Kater states, that he "saw the outer ring separated by numerous dark divisions extremely close, one stronger than the rest dividing the ring about equally." Such surmises, however, require to be confirmed by subsequent observations

[*] See Note, p. 81.

[†] The Author, some years ago, described a method by which the planets (if any) within the orbit of Mercury, may be discovered in the day-time, by means of a simple contrivance for intercepting the solar rays, and the frequent application, by a number of observers, of powerful telescopes, to a certain portion of the sky, in the vicinity of the sun. The details of this plan have not yet been published; but the reader will see them alluded to, in No. V of the Edinburgh Philosophical Journal, for July, 1820, p. 191.

[‡] A *primary* planet is that which revolves round the sun as a center; as Mars, Jnpiter, and Saturn. A *secondary* planet is one which revolves round a primary planet as its center; as the Moon, and the satellites of Jupiter and

COMETS.—Beside the planetary globes to which I have now adverted, there is a class of celestial bodies which occasionally appear in the heavens, to which the name of *Comets* has been given. They are distinguished from the other celestial bodies, by their ruddy appearance, and by a long train of light, called the *tail*, which sometimes extends over a considerable portion of the heavens, and which is so transparent that the stars may be seen through it. The tail is always directed to that part of the heavens which is opposite to the sun, and increases in size as it approaches him, and is again gradually diminished, as the comet flies off to the more distant regions of space. Their apparent magnitude is very different: sometimes they appear only of the bigness of the fixed stars; at other times they equal the diameter of Venus; and sometimes they have appeared nearly as large as the Moon. They traverse the heavens in all directions, and cross the orbits of the planets. When examined through a telescope, they appear to consist of a dark central nucleus, surrounded by a dense atmosphere, or mass of vapors. They have been ascertained to move in long narrow *ellipses* or *ovals*, around the sun; some of them, on their nearest approach to him, having been within a million of miles of his center: and then fly off to a region several thousands of millions of miles distant. When near the sun, they move with amazing velocity. The velocity of the comet which appeared in 1680, according to Sir Isaac Newton's calculation, was 880,000 miles an hour. They appear to be bodies of no great density, and their size seldom exceeds that of the moon. The length of the tails of some comets has been estimated at fifty millions of miles. According to Sir W. Herschel's computations, the solid nucleus, or central part of the comet which appeared in 1811, was only 428 miles in diameter; but the real diameter of the head or nebulous portion of the comet, he computed to be about 127,000 miles. The length of its tail he computed to be above one hundred millions of miles, and its breadth nearly fifteen millions. It was nearest to the earth on the 11th October, when its distance was 113 millions of miles. The number of comets which have occasionally been seen within the limits of our system, since the commencement of the Christian era, is about 500, of which the paths or orbits of more than a hundred have been calculated.

As these bodies cross the paths of the planets in every direction, there is a possibility that some of them might strike against the earth in their approach to the sun; and, were this to happen, the consequences would be awful beyond description. But we may rest assured that that Almighty Being who at first launched them into existence directs all their motions, however complicated; and that the earth shall remain secure against all such concussions from celestial agents, until the purposes of his moral government in this world shall be fully accomplished. What regions these bodies visit, when they pass beyond the limits of our view; upon what errands they are sent; when they again revisit the central parts of our system; what is the difference in their physical constitution, from that of the sun and planets; and what important ends they are destined to accomplish in the economy of the universe; are inquiries which naturally arise in the mind, but which surpass the limited powers of the human understanding at present to determine. Of this, however, we may rest assured, that they were not created in vain; that they subserve purposes worthy of the infinite Creator; and that, wherever he has exerted his power, there also he manifests his wisdom and beneficence.*

Such is a general outline of the leading facts connected with that system to which our earth belongs. Though the energies of Divine Power had never been exerted beyond the limits of this system, it would remain an eternal monument of the Wisdom and Omnipotence of its Author. Independently of the Sun, which is a vast universe in itself, and of the numerous comets which are continually traversing its distant regions, it contains a mass of material existence, arranged in the most beautiful order, two thousand five hundred times larger than our globe. From late observations, there is the strongest reason to conclude that the sun, along with all this vast assemblage of bodies, is carried through the regions of the universe toward some distant point of space, or around some wide circumference, at the rate of more than sixty thousand miles an hour; and if so, it is highly probable, if not absolutely certain, that we shall never again occupy that portion of *absolute space* through which we are this moment passing during all the succeeding ages of eternity.

Such a glorious system must have been brought into existence, to subserve purposes worthy of the

---

Saturn. The primary planets are distinguished from the fixed stars, by the steadiness of their light; not having a *twinkling* appearance, as the stars exhibit.

* The periodical revolutions of the greater number of comets are accomplished only in long periods of time; some of them requiring hundreds and even thousands of years to finish their circuits. But, of late years, two comets have been discovered whose periodic revolutions are extremely short.—These are, 1st. The *comet of Encke*, whose periodic revolution is only 1200 days, or 3 years and three-tenths and becomes visible ten times in 33 years. It was discovered at Marseilles, by M. Pons, on the 28th November. 1818, and soon after M. Encke of Berlin determined its period by incontestable calculations. This comet has since regularly made its appearance. It was seen in Australia in June, 1822, and since that time in Europe, in 1825, 1828, 1832, 1835, and 1838. This comet is very small; its light is feeble; it has no tail, and it is invisible to the naked eye, except in very favorable circumstances.—The other comet to which we allude is distinguished by the name of *Biela's* and sometimes *Gambart's comet*. This comet was first perceived at Johanisberg, on the 27th of February, 1826, by M. Biela, and ten days after by M. Gambart, at Marseilles, who calculated its orbit, and determined the period of its revolution to be 2460 days, or nearly 6¾ years. The predicted appearance of this comet in 1832 produced considerable alarm on the continent, particularly in France; as some German journalists had predicted that it would cross the earth's orbit near the point at which the earth would be at that time, and cause the destruction of our globe. This comet is a small body without a tail, or any appearance whatever of a solid nucleus, and is not distinguishable by the naked eye. It is not improbable that the observations which may hereafter be made on these comets, whose return is so frequent, will lead to more definite and accurate views of the nature and destination of these singular bodies. The only other comet whose period is determined is that which is known by the name of *Halley's comet*. This comet was observed by Dr. Halley in 1682, and, on calculating its elements, he was led to conclude that it was identical with the great comets of 1456, 1531, and 1607; and that its period is 75 or 76 years. He accordingly ventured to predict that it would again return about the latter part of 1758 or the beginning of 1759. It actually reappeared near the end of December, 1758, and arrived at its perihelion on the 13th March, 1759; and it again made its appearance, according to prediction, in September and October, 1835, having been seen in the particular positions previously predicted, a considerable time before it was visible to the naked eye. The appearance of this comet, so near the time predicted by astronomers, is a clear proof of the accuracy which has been introduced into astronomical calculations, and the soundness of the principles on which astronomers proceed. This circumstance likewise shows us that comets in general are *permanent* bodies belonging to that system of which we form a part.

Infinite Wisdom and Benevolence of the Creator. To suppose that the distant globes of which it is composed, with their magnificent apparatus of Rings and Moons, were created merely for the purpose of affording a few astronomers, in these latter times, a peep of them through their glasses, would be inconsistent with every principle of reason; and would be charging Him who is the Source of Wisdom with conduct which we would pronounce to be folly in the sons of men. Since it appears, so far as our observation extends, that matter exists only for the sake of sensitive and intelligent beings, and that the Creator made nothing in vain—it is a conclusion to which we are necessarily led, that the planetary globes are inhabited by various orders of intellectual beings, who participate in the bounty and celebrate the glory of their Creator.

When this idea is taken into consideration, it gives a striking emphasis to such sublime declarations of the Sacred Volume as these:—"All nations before him are as nothing—He sitteth upon the circle of the earth, and the inhabitants thereof are as grasshoppers—The nations are as *the drop of a bucket*—All the inhabitants of the world *are reputed as nothing* in his sight; and he doth according to his will in the armies of heaven and among the inhabitants of the earth—Thou hast made heaven and the heaven of heavens, with all their hosts; and thou preservest them all; and *the host of heaven worshipeth thee*—When I consider thy heavens, *what is man* that thou art mindful of him!" If the race of Adam were the principal intelligences in the universe of God, such passages would be stripped of all their sublimity, would degenerate into mere hyperboles, and be almost without meaning. If man were the only rational being who inhabited the MATERIAL WORLD, as some arrogantly imagine, it would be no wonder at all that God should be "mindful of him," nor could "all the inhabitants of this world," with any propriety, be compared to "a drop of a bucket," and be "reputed as nothing in his sight."—Such declarations would be contrary to fact, if this supposition were admitted; for it assumes that man holds the *principal station* in the visible universe. The expressions—"The heavens, the heaven of heavens," and "the host of heaven worshiping God," would also, on this supposition, degenerate into something approaching to mere inanity. These expressions, if they signify anything that is worthy of an Inspired Teacher to communicate, evidently imply that the universe is vast and extensive, beyond the range of human comprehension—that it is peopled with myriads of inhabitants—that these inhabitants are possessed of intellectual natures, capable of appreciating the perfections of their Creator—and, that they pay him a tribute of rational adoration: "The host of heaven worshipeth thee." So that the language of Scripture is not only consistent with the doctrine of a plurality of worlds, but evidently supposes their existence to all the extent to which the discoveries of modern science can carry us. However vast the universe now appears—however numerous the worlds, and systems of worlds, which may exist within its boundless range—the language of Scripture is sufficiently comprehensive and sublime, to express all the emotions which naturally arise in the mind when contemplating its structure; a characteristic which will apply to no other book, or pretended revelation. And this consideration shows not only the harmony which subsists between the discoveries of Revelation and the discoveries of Science, but also forms, by itself, a strong presumptive evidence that the records of the Bible are authentic and divine.[*]

Vast as the Solar System we have now been contemplating may appear, it is but a mere point in the map of creation. To a spectator placed in one of the stars of the seventh magnitude, not only the glories of this world, and the more resplendent scenes of the planet Saturn, but even the sun himself would entirely disappear, as if he were blotted out of existence. 'Were the sun," says Mr. Addison, "which enlightens this part of the creation, with all the host of the planetary worlds that move about him, utterly extinguished and annihilated, they would not be missed by an eye that could take in the whole compass of nature, more than a grain of sand upon the sea-shore. The space they possess is so exceedingly little in comparison of the whole, that it would scarcely make a blank in creation."

The Fixed Stars.—When we pass from the planetary system to other regions of creation, we have to traverse, in imagination, a space so immense, that it has hitherto baffled all the efforts of science to determine its extent. In these remote and immeasurable spaces are placed those immense luminous bodies usually denominated the *fixed stars.* The nearest stars are, on good grounds, concluded to be at least *twenty billions* of miles distant from our globe—a distance through which *light* (the swiftest body in nature) could not travel in the space of three years; and which a ball, moving at the rate of 500 miles an hour, would not traverse in four millions, five hundred thousand years, or 750 times the period which has elapsed since the Mosaic creation. But how far they may be placed beyond this distance, no astronomer will pretend to determine. The following consideration will prove, to those unacquainted with the mathematical principles of astronomy, that the stars are placed at an immeasurable distance. When they are viewed through a telescope which magnifies objects a thousand times, they appear no larger than to the naked eye; which circumstance shows, that though we were placed at the thousandth part of the distance from them at which we now are, they would still appear only as so many shining *points;* for we should still be distant from the nearest of them, twenty thousand millions of miles: or, in other words, were we transported several thousands of millions of miles from the spot we now occupy, though their numbers would appear exceedingly increased, they would appear no larger than they do from our present station; and we behooved to be carried forward thousands of millions of miles farther in a long succession, before their discs appeared to expand into large circles like the moon. Sir W. Herschel viewed the stars with telescopes magnifying from *one to two or three thousand times*, yet they still appeared only as brilliant points, without any sensible discs or increase of diameter. This circumstance incontestably proves the two following things: 1. That the stars are *luminous bodies*, which shine by their own native light; otherwise they could not be perceived at such vast distances. 2. That they are bodies of an immense size, not inferior to the sun; and many of them, it is probable, far exceed that luminary in bulk and splendor.[†]

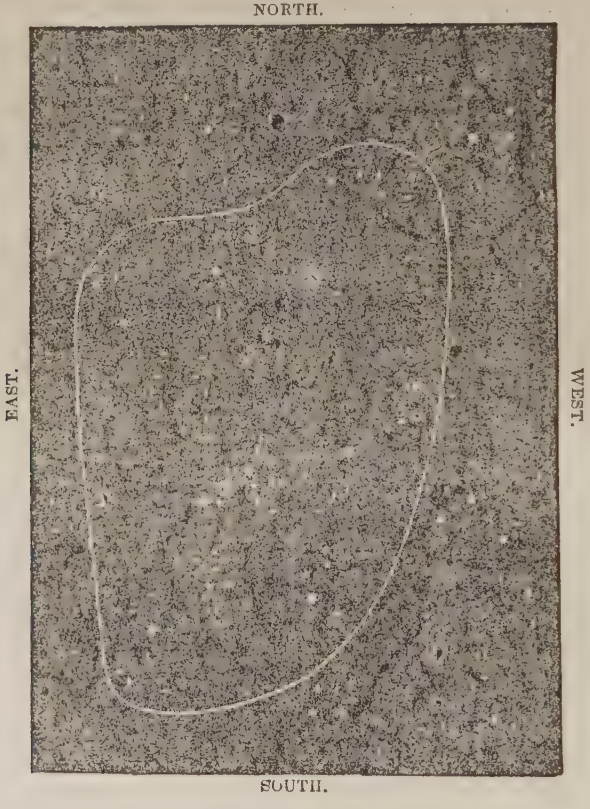
---

[*] See Appendix, Note VI.

[†] Professor Bessel of Konigsberg appears to have lately ascertained the annual parallax of the star 61 *Cygni*, which he has determined to be somewhat less than *one-third of a second*, and consequently its distance must be 62,481,500,000,000, or sixty-two *billions*, four hundred and eighty-one thousand five hundred millions of miles—a distance which *light*, swift

For the conveniency of reference to particular objects and regions in the heavens, the stars have been arranged into different groups and *constellations.* The number of constellations recognized by modern astronomers is about 94; of which 12 are contained in the *Zodiac*, or that zone in the heavens in which the sun, moon, and planets are seen to perform their real or apparent revolutions; 35 are reckoned *North* of the zodiac, and 47 to the *South,* called the *Northern* and *Southern* constellations. These constellations are generally depicted on celestial globes and planispheres, as if they were represented by various animals and hieroglyphic objects, which give such exhibitions of the heavens a very grotesque and *unnatural* appearance. We have therefore given, in the following cut (fig. 23), a representation of the constellation *Orion,* with the adjacent stars, on a more simple and *natural* plan, to show the manner in which the celestial constellations might be depicted on globes and planispheres, so as to make them resemble as much as possible their appearance in the heavens. This constellation makes a splendid appearance in the southern parts of the heavens during our winter months. The two large stars near the top toward the left, are *Betelguese* and *Bellatrix;* the three equidistant stars, near the middle, are Orion's *belt,* called in the book of Job, the "*bands* of Orion." The large star, near the bottom, on the right, is *Rigel,* a star of the first magnitude. A white line is drawn around this constellation to define its boundaries, and, in this way the form and limits of all the other constellations might be distinguished.

Fig. 23.



The stars, on account of the difference in their apparent magnitudes, have been distributed into several classes or orders. Those which appear largest are called stars of the *first* magnitude; next to those in luster, stars of the second magnitude, and so on to stars of the *sixth* magnitude, which are the smallest that can be distinguished by the naked eye. Stars of the seventh, eighth, ninth, tenth, &c., magnitudes, which cannot be seen by the naked eye, are distinguished by the name of the *telescopic* stars. Not more than a thousand stars can be distinguished by the naked eye in the clearest winter night; but by means of the telescope, millions have been discovered.* And as it is probable, that by far the greater part lie beyond the reach of the best glasses which have been, or ever will be, constructed by man—the real number of the stars may be presumed to be beyond all human calculation or conception, and perhaps beyond the grasp of angelic comprehension.

In consequence of recent discoveries, we have now the strongest reason to believe, that all the stars in the universe are arranged into clusters, or groups, which astronomers distinguish by the

---

as its motion is, would require 10 years and 114 days to fly across this mighty interval; and a cannon ball, moving 500 miles every hour, would require fourteen millions, two hundred and fifty thousand years before it could move across the same interval.—For a more detailed account of this discovery of Bessel, the reader is referred to the author's volume entitled "Sidereal Heavens."

* See page 21.

name of Nebulæ, or Starry Systems, each nebula consisting of many thousands of stars. The nearest nebula is that whitish space or zone which is known by the name of the *Milky Way*, to which our sun is supposed to belong. It consists of many hundreds of thousands of stars. When Sir W Herschel examined this region with his powerful telescopes, he found a portion of it, only fifteen degrees long, and two broad, which contained *fifty thousand* stars large enough to be distinctly counted; and he suspected twice as many more, which, for want of sufficient light in his telescope, he saw only now and then. More than three thousand nebulæ have already been observed; and, if each of them contain as many stars as the Milky Way, several hundreds of millions of stars must exist, even within that portion of the heavens which lies open to our observation. Beside those Nebulæ which are resolvable into stars by telescopes, there are nebulous bodies in the heavens, of vast extent, such as the nebula in the sword of Orion, which the most powerful telescopes have hitherto been unable to resolve into stars. These are found in different degrees of condensation—from the resemblance of an irregular dusky cloud to the appearance of a well-defined body of faintish light, condensed to a bright spot in the center. They appear to be a species of fine luminous matter, distinct from stars and planets, diffused in immense masses throughout the spaces of the universe. It is an opinion now generally entertained that these self-luminous portions of matter are the chaotic materials out of which new suns and worlds may be formed under the superintendence of Omnipotence—and that each mass of this substance is gradually concentrating itself by the effect of its own gravity, and of the circular motions of which it is susceptible—into denser masses, so as ultimately to effect the arrangement and establishment of sidereal systems.

It appears, from numerous observations, that *various changes* are occasionally taking place in the regions of the stars. Several stars have appeared for a while in the heavens, and then vanished from the sight. Some stars which were known to the ancients, cannot now be discovered; and stars are now distinctly visible, which were to them unknown. A few stars have gradually increased in brilliancy, while others have been constantly diminishing in luster. Certain stars, to the number of fifteen or upwards, are ascertained to have a periodical increase and decrease of their luster, sometimes appearing like stars of the first or second magnitude, sometimes diminishing to the size of the fourth or fifth magnitude, and sometimes altogether disappearing to the naked eye. The late discoveries respecting *double and triple* stars are particularly worthy of attention. Some stars, which, to the naked eye, appear single, when examined by good telescopes, are found to consist of two, three, or more stars. In reference to *double stars*, one of the two is generally considerably smaller than the other, and it is now ascertained that, in many instances, the smaller star has a circular or elliptical motion around the larger. About 6000 double stars have already been detected; and between 40 and 50 of these bodies have been ascertained beyond doubt to form revolving systems. Some of these require 1600, others 1200, and others about 452 years to complete their revolutions; while some others finish their circuits in the short periods of 55, 43, and even 30 years. So that here we have *Suns* revolving around suns, and systems of worlds revolving around systems of worlds, in various combinations, throughout the tracts of immensity. It also appears that changes are taking place among the Nebulæ—that several nebulæ are formed by the decomposition of larger nebulæ, and that many nebulæ of this kind are at present detaching themselves from the nebulæ of the Milky Way. These changes seem to indicate, that mighty movements and vast operations are continually going on in the distant regions of creation, under the superintendence of the Sovereign of the Universe, upon a scale of magnitude and grandeur which overwhelms the human understanding.

To explore more extensively the region of the starry firmament; to mark the changes that are taking place; to ascertain all the changeable stars; to determine the periodical variations of their light; the revolutions of double and triple stars; and the motions and other phenomena peculiar to these great bodies—will furnish employment for future enlightened generations; and will perhaps form a part of the studies and investigations of superior intelligences, in a higher sphere of existence, during an indefinite lapse of ages.

If every one of these immense bodies be a Sun, equal or superior to ours, and encircled with a host of planetary worlds, as we have every reason to conclude to be the case,* how vast must be the extent of creation! how numerous the worlds and beings which exist within its boundless range! and how great, beyond all human or angelic conception, must be the Power and Intelligence of that glorious Being who called this system from nothing into existence, and continually superintends all its movements! The mind is bewildered and confounded when it attempts to dwell on this subject; it feels the narrow limits of its present faculties; it longs for the powers of a seraph, to enable it to take a more expansive flight into those regions which "eye hath not seen;" and, while destitute of these, and chained down to this obscure corner of creation, it can only exclaim, in the language of inspiration, "Who can by searching find out God?—Great is our Lord, and of great power: his understanding is infinite!—Great and marvelous are thy works, Lord God Almighty!—Who can utter the mighty acts of Jehovah! who can show forth *all* his praise!"

After what has now been stated in relation to the leading facts of Astronomy, it would be needless to spend time in endeavoring to show its connection with Religion. It will at once be admitted, that all the huge globes of luminous and opaque matter to which we have adverted, are the workmanship of Him "who is wonderful in counsel, and excellent in working;" and form a part of the dominions of that august Sovereign, "whose kingdom ruleth over all." And shall it ever be insinuated, that this subject has no relation to the great object of our adoration? and that it is of no importance in our views of the Divinity, whether we conceive his dominions as circumscribed within the limits of little more than 25,000 miles, or as embracing an extent which comprehends innumerable worlds! The objects around us in this sublunary sphere, strikingly evince the superintendency, the wisdom, and benevolence of the Creator: but this science demonstrates, beyond all other departments of human knowledge, the GRANDEUR and MAGNIFICENCE of his operations; and raises the mind to sublimer views of his attributes than can be acquired by the contemplation of any other objects. A serious contemplation of the sublime objects which Astronomy has explored, must therefore have a tendency to inspire us with profound veneration of the Eternal Jehovah—to humble us in the dust before his august presence—to excite admiration of his condescension and grace in the work of redemption—to show us the littleness of this world, and the insignificancy of those riches and honors to which ambitious men aspire with so much labor and anxiety of mind—to demonstrate the glory and magnificence of God's universal kingdom—to convince us of the infinite sources of varied felicity which he has in his power to communicate to holy intelligences—to enliven our hopes of the splendors of that "exceeding great and eternal weight of glory," which will burst upon the spirits of good men, when they pass from this region of mortality—and to induce us to aspire with more lively ardor after that heavenly world, where the glories of the Deity, and the magnificence of his works, will be more clearly unfolded.

---

* See pp. 19, 28.

If, then, such be the effects which the objects of astronomy have a tendency to produce on a devout and enlightened mind—to call in question the propriety of exhibiting such views in religious publications, or in the course of religious instructions, would be an approach to impiety, and an attempt to cover with a vail the most illustrious visible displays of Divine glory.—It forms a striking evidence of the depravity of man, as well as of his want of true taste, and of a discernment of what is excellent, that the grandeur of the nocturnal heavens, and the perfections of Deity they proclaim, are beheld with so much apathy and indifference by the bulk of mankind. Though "the heavens declare the glory of God," in the most solemn and impressive language, adapted to the comprehension of every kindred and every tribe, yet "a brutish man knoweth not, neither doth a fool understand this." They can gaze upon these resplendent orbs with as little emotion as the ox that feeds on the grass, or as the horse that drags their carcasses along in their chariots. They have even attempted to ridicule the science of the heavens, to caricature those who have devoted themselves to such studies, and to treat with an indifference, mingled with contempt, the most august productions of Omnipotence. Such persons must be considered as exposing themselves to that Divine denunciation—"Because they regard not the works of Jehovah, neither consider the operations of his hands, he will destroy them, and not build them up." If the structure of the heavens, and the immensity of worlds and beings which they contain, were intended by the Creator to *adumbrate*, in some measure, his invisible perfections, and to produce a sublime and awful impression on the minds of all created intelligences,* it must imply a high degree of disrespect to the Divinity, willfully to overlook these astonishing scenes of Power and Intelligence. It is not a matter of mere taste or caprice, whether or not we direct our thoughts to such subjects, but an imperative duty, to which we are frequently directed in the word of God; the *willful neglect* of which, where there is an opportunity of attending to it, must subject us to all that is included in the threatening now specified, if there be any meaning in language.

That the great body of professed Christians are absolute strangers to the sublime sentiments which a serious contemplation of the heavens inspires, must be owing, in part, to the minds of Christian parents and teachers not having been directed to such subjects, or to the views they entertain respecting the relation of such contemplations to the objects of religion. In communicating religious instructions in reference to the attributes of God, the heavens are seldom referred to, except in such a vague and indefinite manner as can produce no deep nor vivid impression on the mind; and many pious persons whose views have been confined to a narrow range of objects, have been disposed to declaim against such studies, as if they had a tendency to engender pride and self-conceit, and as if they were even dangerous to the interests of religion and piety. How very different were the feelings and the conduct of the sacred writers! They call upon every one of God's intelligent offspring to "stand still and consider the wondrous works of the Most High;" and describe the profound emotions of piety which the contemplation of them produced on their own minds: "Lift up your eyes on high, and behold! Who hath created these things? The heavens declare the glory of God, and the firmament showeth his handiwork. When I *consider* thy heavens, the work of thy fingers, the moon and the stars, which thou hast ordained; what is man, that thou art mindful of him? and the son of man, that thou visitest him? Thou, even thou, art Lord alone: thou hast made heaven, and the heaven of heavens, with all their host, and thou preservest them all; and the hosts of heaven worship thee. All the gods of the nations are idols; but the Lord MADE THE HEAVENS; honor and majesty are before him. Jehovah hath prepared his THRONE in the heavens; and his kingdom ruleth over all.—Sing praises unto God, ye kingdoms of the earth, to him that rideth on the heaven of heavens. Ascribe ye POWER to our God; for his strength is in the heavens. Praise him for his mighty acts, praise him *according to his excellent greatness*."—If we would enter with spirit into such elevated strains of piety, we must not content ourselves with a passing and vacant stare at the orbs of heaven, as if they were only so many brilliant *studs* fixed in the canopy of the sky; but must "*consider*" them with fixed attention, in all the lights in which revelation and science have exhibited them to our view, if we wish to praise God for his mighty works, and "*according to his excellent greatness*." And, for this purpose, the conclusions deduced by those who have devoted themselves to celestial investigations, ought to be presented to the view of the intelligent Christian, that he may be enabled to "speak of the glory of Jehovah's kingdom, and to talk of his power."

NATURAL PHILOSOPHY.

Having, in the preceding sketches, considerably exceeded the limits originally prescribed for this department of my subject, I am reluctantly compelled to dispatch the remaining sciences with a few brief notices.

The object of *Natural Philosophy* is, to observe and describe the phenomena of the material universe, with a view to discover their causes, and the laws by which the Almighty directs the movements of all bodies in heaven and on earth. It embraces an investigation of the laws of gravitation, by which the planets are directed in their motions; the laws by which water, air, light, and heat, are regulated, and the effects they produce in the various states in which they operate; the nature of colors, sounds, electricity, galvanism, and magnetism, and the laws of their operation; the causes which operate in the production of thunder, lightning, luminous and fiery meteors, hail, rain, snow, dew, and other atmospherical phenomena. In short, it embraces all the objects of Natural History formerly alluded to, with a view to ascertain the causes of their varied appearances, and the principles that operate in the changes to which they are subject; or, in other words, the laws by which the diversified phenomena of universal nature are produced and regulated. One subordinate use of the knowledge derived from this science, is, to enable us to construct all those mechanical engines which facilitate human labor, and increase the comforts of mankind, and all those instruments which tend to enlarge our views of the operations of nature. A still higher and nobler use to which philosophy is subservient, is to demonstrate the Wisdom and Intelligence of the Great First Cause of all things, and to enlarge our conceptions of the admirable contrivance and design which appear in the different departments of universal nature. In this view, it may be considered as forming a branch of *Natural Theology*, or, in other words, a branch of the religion of angels, and of all other holy intelligences.

---

* See pp. 21, 24.

This department of natural science has generally been divided into the following branches:—

I. Mechanics.—This branch, considered in its most extensive range, includes an investigation of the general properties of matter; such as solidity, extension, divisibility, motion, attraction, and repulsion—the law of gravitation, and of central forces, as they appear to operate in the motions of the celestial bodies; and on the surface of our globe, in the phenomena of falling bodies, the motions of projectiles, the vibration of pendulums, etc.,—the theory of machines, the principles on which their energy depends; the properties of the mechanical powers—the *lever*, the *wheel* and *axle*, the *pulley*, the *inclined plane*, the *wedge*, and the *screw*,—and the effects resulting from their various combinations. From the investigations of philosophers on these subjects, we learn the laws by which the great bodies of the universe are directed in their motions; the laws which bind together the different portions of matter on the surface of the earth, and which regulate the motions of animal, vegetable, and inanimate nature; and the principles on which cranes, mills, wheel-carriages, thrashing-machines, pile-engines, locomotive carriages, and other engines, are constructed; by means of which man has been enabled to accomplish operations far beyond the limits of his own physical powers.

Without a knowledge of the laws of motion, and assistance from the combined effects of the mechanical powers, man would be a very limited being, his enjoyments would be few, and his active energies confined within a very narrow range. In a savage state, ignorant of manufactures, agriculture, architecture, navigation, and the other arts which depend upon mechanical combinations, he is exposed, without shelter, to the inclemencies of the seasons; he is unable to transport himself beyond seas and oceans, to visit other climes, and other tribes of his fellow-men; he exists in the desert, comfortless and unimproved; the fertile soil, over which he roams, is covered with thorns and briers, and thickets, for the haunt of beasts of prey; his enjoyments are little superior to those of the lion, the hyena, and the elephant, while he is much their inferior in point of agility and physical strength. But, when philosophy has once demonstrated the principles of Mechanics, and introduced the practice of the useful Arts, "the wilderness and the solitary place are made glad, and the desert rejoices and blossoms as the rose." Cities are founded, and gradually rise to opulence and splendor; palaces and temples are reared; the damp cavern, and the rush-built hut, are exchanged for the warm and comfortable apartments of a substantial mansion; ships are built, and navigated across the ocean; the treasures of one country are conveyed to another; an intercourse is carried on between the most distant tribes of mankind; commerce flourishes, and machinery of all kinds is erected for facilitating human labor, and promoting the enjoyments of man. And, when the principles and the practice of "pure and undefiled religion" accompany these physical and mechanical operations, love and affection diffuse their benign influence; the prospect brightens as years roll on, and man advances, with pleasure and improvement, to the scene of his high destination.

II. Hydrostatics treats of *the pressure and equilibrium of fluids.* From the experiments which have been made in this branch of philosophy, the following important principles, among many others, have been deduced:—

(1.) *That the surface of all waters which have a communication while they are at rest, will be perfectly level.*—This principle will be more clearly understood by an inspection of the following figures. If water be poured into the tube A (fig. 24), it will run through the horizontal tube E, and rise in the opposite tube B, to the same hight at which it stands at A. It is on this principle that water is now conveyed under ground, through conduit pipes, and made to rise to the level of the fountain whence it is drawn. The city of Edinburgh, a considerable part of which is elevated above the level of the surrounding country, is supplied with water from a reservoir on the Pentland hills, several miles distant. The water is conveyed in leaden pipes down the declivity of the hill, along the interjacent plain, and up to the entrance of the castle, whence it is distributed to all parts of the city. If the point A represent the level of the reservoir, C D will represent the plain along which the water is conveyed, and B the elevation to which it rises on the Castle-hill. On the same principle, and in a similar manner, the city of London is supplied with water from water-works at the London bridge. Had the ancients been acquainted with this simple, but important principle, it would have saved them the labor and expense of rearing those stupendous works of art, the *Aqueducts*, which consisted of numerous arches of vast size, and sometimes piled one above another.

Fig. 24.

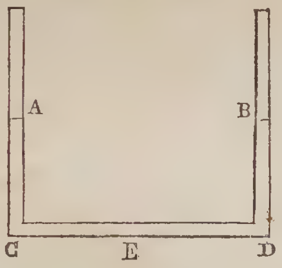


Fig. 25 represents the *syphon*, the action of which depends upon the pressure of the atmo-

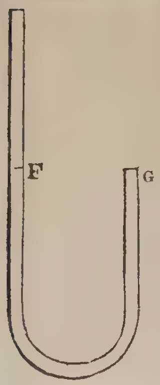
Fig. 25



sphere. If this instrument be filled with water, or any other liquid, and the shorter leg G plunged to the bottom of a cask, or other vessel containing the same liquid, the water will run out at the longer leg F, until the vessel be emptied, in consequence of the atmospheric pressure upon the surface of the liquid. On this principle water may be conveyed over a rising ground to any distance, provided the perpendicular hight of the syphon above the surface of the water in the fountain does not exceed thirty-two or thirty-three feet. On the same principle are constructed the *fountain at command*, the *cup of Tantalus*, and other entertaining devices. The same principle, too, enables us to account for springs which are sometimes found on the tops of mountains, and for the phenomena of *intermitting* springs, or those which flow and stop by regular alternations.

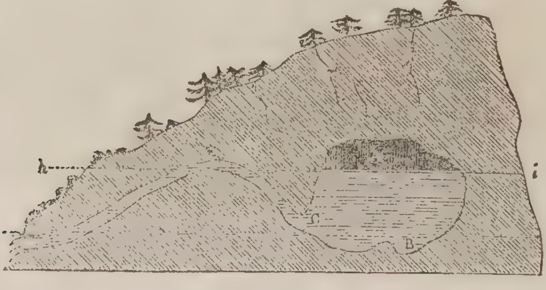
The following figure will explain the nature of intermitting springs. Suppose A B a cavity or receptacle of water formed in the bowels of a hill where the spring is situated, which gradually fills with water like other reservoirs, and that by the interposition of some stratum of rock or other substance, the tube C D, which conveys the water to the spring or mouth where it issues—is bent in the form of a syphon; whenever the reservoir A B is filled as high as the bend of the tube, or to the level of *h i*, the water will rise in the tube, and begin to flow into the spring, which will continue until the reservoir be exhausted. While this process is going on, the water in the spring will rise, and as soon as the reservoir is exhausted, the water will appear to fall in the well of the spring, and will continue to fall until the reservoir is again supplied to the hight of the syphon when the process of filling will be again renewed It is obvious that unless the water in the reservoir rises above the hight of the bend of the syphon E, the well cannot be filled.

(2.) *Any quantity of fluid, however small, may be made to counterpoise any quantity, however large* This is what has generally been termed the Hydrostatical Paradox; and from this principle it follows, that a given quantity of water may exert a force several hundred times greater or less, according to the manner in which it is employed This force depends on the *hight* of the column of water, independent of its quantity; for its *pressure* depends on its perpendicular hight. By means of water conveyed through a very small perpendicular tube, of great length, a very strong hogshead has been burst to pieces, and the water scattered about with incredible force. On this principle, the *hydrostatic press*, and other engines of immense power, have been constructed.

(3.) *Every body which is heavier than water, or which sinks in it, displaces so much of the water as is equal to the bulk of the body immersed in the water.*—On this principle, the specific gravities, or comparative weight, of all bodies are determined. It appears to have been first ascertained by Archimedes, and by means of it, he determined that the golden crown of the king of Syracuse had been adulterated by the workmen. From this principle we learn, among many other things, the specific gravity of the human body; and that four pounds of cork will preserve a person weighing 135 pounds from sinking, so that he may remain with his head completely above water.

Hydraulics, which has sometimes been treated as a distinct department of mechanical philosophy, may be considered as a branch of Hydrostatics. It teaches us what relates to the *motion of fluids*, and how to estimate their velocity and force On the principles of this science, all machines worked by water are constructed—as steam-engines, water-mills, common and forcing pumps, syphons, fountains, and fire-engines.

Fig. 26.



III. Pneumatics.—This branch of philosophy treats of the nature and properties of the atmosphere, and of their effects on solid and fluid bodies. From this science we learn that air has *weight*, and presses on all sides like other fluids; that the pressure of the atmosphere upon the top of a mountain is less than on the plain beneath; that it presses upon our bodies with the weight of several thousand pounds more at one time than at another; that air can be compressed into forty thousand times less space than it naturally occupies; that it is of an elastic or expansive nature, and that the force of its spring is equal to its weight; that its elasticity is increased by heat; that it is necessary to the production of sound, the support of flame and animal life, and the germination and growth of all kinds of vegetables.

These positions are proved and illustrated by such experiments as the following:—The general *pressure* of the atmosphere is proved by such experiments as those detailed in Note II of the Appendix. The following experiment proves that air is *compressible*. If a glass tube, open at one end, and close at the other, be plunged, with the open end downward, into a tumbler of water, the water will rise a little way in the tube; which shows, that the air which filled the tube is compressed by the water into a smaller space. The *elasticity* of air is proved by tying up a bladder, with a very small quantity of air within it and putting it under the receiver of an air-pump, when it will be seen gradually to inflate, until it becomes of its full size. A similar effect would take place, by carrying the bladder to the higher regions of the atmosphere. On the compression and elasticity of the air, depends the construction of that dangerous and destructive instrument, the Air-gun. That it is capable of being rarefied by heat, is proved by holding to the fire a half-blown bladder, slightly tied at the neck, when it will dilate to nearly its full size; and if either a *full blown* bladder, or a thin glass bubble filled with air, is held to a strong fire, it will burst. The elasticity of the air is such, that Mr. Boyle, by means of an air-pump, caused it to dilate until it occupied fourteen thousand times the space that it usually does. That the air is necessary to sound, flame, animal and vegetable life, is proved by the following experiments:—When the receiver of an air-pump is exhausted of its air, a cat, a mouse, or a bird, placed in it, expires in a few moments, in the greatest agonies. A bell rung in the same situation produces no sound; and a lighted candle is instantly extinguished. Similar experiments prove that air is necessary for the flight of birds, the ascent of smoke and vapors, the explosion of gunpowder, and the growth of plants; and that all bodies descend equally swift in a place void of air; a guinea and a feather being found to fall to the bottom of an exhausted receiver at the same instant.

On the principles which this science has established have been constructed the air-pump, the barometer, the thermometer, the diving-bell, the hygrometer, the condenser, and various other instruments, which have contributed to the comfort of human life, and to the enlargement of our knowledge of the constitution of nature.

IV. Acoustics.—This science treats of the nature, the phenomena, and the laws of *sound*, and the theory of musical concord and harmony.—From the experiments which have been made on this subject, we learn, that air is essential to the production of sound; that it arises from *vibrations* in the air, communicated to it by vibrations of the sounding body; that these vibrations, or aerial pulses, are propagated all around in a spherical undulatory manner; that their density decreases as the squares of the distances from the sounding body increase; that they are propagated together in great numbers from different bodies without disturbance or confusion, as is evident from concerts of musical instruments; that water, timber, and flannel, are also good conductors of sound; that sound travels at the rate of 1142 feet in a second, or about thirteen miles in a minute;[*] that the softest whisper flies as fast as the loudest thunder; and that the utmost limits, within which the loudest sounds, produced by artificial means, can be heard, is 180 or 200 miles;[†] that sound, striking against an obstacle, as the wall of a house, may, like light, be reflected, and produce another sound, which is called an *echo;* and that, after it has been reflected from several places, it may be collected into one point or focus, where it will be more audible than in any other place.

The intensity of sound increases or diminishes when the elasticity of the air increases or diminishes, either by heat or by compression. Hence, in proportion as the air is rarefied under the receiver of an air-pump, or in the ascent of lofty mountains, sound loses its force. Air communicates its vibrations to the sonorous bodies with which it is in contact. Hence a string of an instrument causes another stretched beside it to vibrate. A noise without makes the windows of an apartment to resound, and the discharge of cannons, and peals of thunder, cause buildings, and even whole villages to shake. Euler tells us of a man who, by different inflections of his voice, made a glass vibrate so as almost to break it.—When the velocity of sound is known, the distance of certain objects may be determined. If a flash of a gun be observed, and the number of seconds or pulsations which elapse between seeing the flash and hearing the report, be counted, this number multiplied by 1142, the assumed velocity of sound per second, will give the distance of the observer from the center of vibration. If, in a thunder storm, I can count five pulsations, from the instant of seeing the lightning until the report of the thunder be heard, the distance of the thunder cloud will be $1142 \times 5 = 5710$ feet, that is, an English mile and 430 feet. Were the thunder to be heard within a second of the time of seeing the flash, it would indicate that the thunder was within 380 yards of the observer, and consequently, that he is within the sphere of danger.—In estimating such distances 4½ seconds, at an average, may be reckoned for every mile.

On the principles above stated we may account for the various phenomena of sounds and the diversified *echoes* which are heard in various places, which both amuse and sometimes puzzle the observers—and on the same principles whispering galleries, such as that in St. Paul's church, London, speaking and hearing trumpets—wind and stringed instruments—the *Harmonica Celestina*, and other acoustic instruments, are constructed.

V. Optics.—This branch of philosophy treats of vision, light, and colors, and of the various phenomena of visible objects produced by the rays of light, reflected from mirrors, or transmitted through lenses. From this science we learn, that light flies at the rate of nearly twelve millions of miles every minute — that it moves in straight lines—that its particles may be several thousands of miles distant from each other—that every visible body emits particles of light from its surface, in all directions—that the particles of light are *exceedingly small;* for a lighted candle will fill a cubical space of two miles every way with its rays, before it has lost the least sensible part of its substance; and millions of rays, from a thousand objects will pass through a hole not larger than the point of a needle, and convey to the mind an idea of the form, position, and color, of every individual object—that the intensity, or degree of light decreases, as the square of the distance from the luminous body increases; that is, at two yards distance from a candle, we shall have only the fourth part of the light we should have at the distance of one yard; at three yards distance, the ninth part; at four yards, the sixteenth part, and so on—that glass *lenses* may be ground into the following forms: *plano-convex*, *plano-con-*

---

[*] The velocity of sound has been somewhat differently estimated by different experimenters. Mr. Boyle estimated its velocity at 1200 feet; the Florentine Academicians at 1148 feet; the French Academicians at 1172 feet *per second.* It is reckoned by some modern philosophers that 1120 feet per second may be reckoned as a medium estimate: The experiments of Flamstead, Halley, and Derham, which were considered as having been accurately performed, give 1142 feet per second, as the average velocity of sound—which is sometimes modified by the direction of the wind and local circumstances.

[†] In the war between England and Holland, in 1672, the noise of the guns was heard in those parts of Wales which were estimated to be two hundred miles distant from the scene of action. But the sounds produced by volcanoes have been heard at a much greater distance; some instances of which are stated in Chap. IV, Sect. 2. Several other facts, in relation to sound are detailed in Chap. III, Art. *Acoustic Tunnels.*

cave, double convex, double concave, and *meniscus*, that is, convex on one side, and concave on the other—that specula, or mirrors, may be ground into either a spherical, parabolical, or cylindrical form—that, by means of such mirrors and lenses, the rays of light may be so modified as to proceed either in a *diverging, converging*, or *parallel* direction, and the images of visible objects represented in a variety of new *forms, positions*, and *magnitudes*,—that every ray of white light may be separated into seven primary colors: *red, orange, yellow, green, blue, indigo*, and *violet*—that the variegated coloring which appears on the face of nature is not in the objects themselves, but in the light which falls upon them—that the *rainbow* is produced by the refraction and reflection of the solar rays in the drops of falling rain—that the rays of light are refracted, or bent out of their course, when they fall upon glass, water, and other mediums—that the light of the sun may be collected into a point or focus, and made to produce a heat more intense than that of a furnace[*]—that the rays from visible objects, when reflected from a concave mirror, converge to a focus, and paint an image of the objects before it, and that when they pass through a convex glass, they depict an image behind it.

On these and other principles demonstrated by this science, the Camera Obscura, the Magic Lantern, the Phantasmagoria, the Kaleidoscope, the Heliostata, the Micrometer—Spectacles, Opera Glasses, Prisms, single, compound, lucernal, and solar Microscopes, reflecting and refracting Telescopes, and other optical instruments, have been constructed, by means of which the natural powers of human vision have been wonderfully increased, and our prospects into the works of God extended far beyond what former ages could have conceived.

Connected with the science of Optics, it may be proper to notice a late discovery for fixing the images formed by convex lenses, distinguished by the name of the DAGUERREOTYPE. Almost every one knows the effects produced by the *Camera Obscura*. A convex glass placed in an opening in a window-shutter in a dark room, or in a box constructed for the purpose, forms, on a white screen, placed at its focal distance, a beautiful picture of all the objects which are opposite to it, in their exact proportions, symmetry, and colors. But this picture evanishes the moment the lens or the screen is removed. The Daguerreotype is an art by which this picture or image may be rendered permanent. It derives its name from M. Daguerre, a member of the French Academy of Fine Arts, who was in partnership with M. Neiper, who, as early as 1814, had commenced researches on this subject; but Daguerre had given up the idea of being able to bring his methods to perfection, until about the year 1838, when the effects produced by his art began to excite a considerable degree of attention; and as a reward for disclosing the process and publishing it to the world, the French government bestowed on the inventor and his partner an annuity of ten thousand francs (£416 13s. 4*d*.): M. Arago, when alluding to this discovery, has the following remark: "No person has ever witnessed the neatness of outline, precision of form, the truth of coloring, and the sweet gradations of tint, displayed by the Camera, without regretting that an imagery so exquisite and so faithful to nature could not be made to fix itself permanently on the tablet of the machine—who has not put up his aspiration that some means might be discovered by which to give reality to shadows so lovely! Yet in the estimation of all, such a wish seemed destined to take its place among other dreams of beautiful things—among the glorious but impracticable conceptions in which men of science and ardent temperament have sometimes indulged. *This dream*, notwithstanding, *has just been realized*."

Our limits will not permit to give a detail of the process by which the effect now stated is produced. We shall just state the following general outline.—The designs taken by the Daguerreotype are executed upon thin plates of silver plated on copper. The silver must be of the purest kind, and the thickness of both metals not to exceed that of a stout card. Before placing it in the Camera the following operations are requisite: 1. The plate must be cleansed and highly polished. For this purpose a little of fine pumice powder is put into a muslin bag and shaken over the plate, and it is then rubbed gently with cotton dipped in olive oil. Diluted nitric acid is then rubbed over the plate with cotton, and then rubbed again with pumice and dry cotton; and afterward the plate is to be subjected to a strong heat. 2. The plate has to receive a coating of Iodine. To accomplish this the plate is fixed upon a board, and then put into a box containing a little dish with iodine divided into small pieces, and allowed to remain until it is covered with a *gold-colored* coating, which process must be conducted in a darkened apartment 3. The Camera is next placed in the front of the landscape or object, and as soon as the focus is adjusted, the light is excluded, and the plate put in, when, in the course of a few minutes, and in some cases, in a few seconds, a perfect picture or design is obtained. I have seen a portrait of an individual taken in this way in the course of half a minute. 4. The plate is next placed over the vapor of mercury to bring out the image, which is not visible when withdrawn from the Camera The image is not visible until after the lapse of several minutes. 5. The coating on which the design was impressed is to be removed in order to preserve it from being decomposed by the rays of light. To do this, the plate is placed in a trough containing common water, plunging and withdrawing it immediately, and then plunging it into a solution of salt and water until the yellow coating has disappeared.

Such is a very abridged sketch of the photogenic operations of M. Daguerre. When finished in a perfect way, the designs thus taken on the plate are exceedingly beautiful and correct, and will bear to be inspected with a considerable magnifying power, so that the most minute portions of the objects delineated may be perceived; and it has been discovered that an etching of the design can be taken in the common way, and from that again any number of electrotype copies can be produced. M. Claudet, the patentee of this invention at the Adelaide gallery, London, has made several improvements, particularly in taking likenesses. He is now enabled to take a likeness in one second, and even less—in the twinkling of an eye, and to give the portraits so made any background that may be desired.

---

[*] This is produced by means of lenses, or mirrors, of a large diameter, called burning-glasses. By these instruments, the hardest metals, on which common fires, and even glass-house furnaces, could produce no effect, have been melted in a few seconds. M. Villette a Frenchman, nearly a century ago, constructed a mirror, three feet eleven inches in diameter, and three feet two inches in focal distance, which melted *copper ore* in eight seconds, *iron ore* in twenty-four seconds, a fish's tooth in thirty-two seconds, *cast iron* in sixteen seconds, a silver sixpence in seven seconds, and *tin* in three seconds. This mirror condensed the solar rays 17,257 times, a degree of heat which is about *four hundred and ninety times* greater than common fire. Mr. Parker, of London, constructed a lens three feet in diameter, and six feet eight inches focus, which weighed 212 lbs. It melted twenty grains of gold in four seconds, and ten grains of platina in three seconds. The power of burning-glasses is, *as the area of the lens directly, and the square of the focal distance inversely*—or, in other words, the broader the mirror or lens, and the shorter the focal distance, the more intense is the heat produced by such instruments. A globular decanter of water makes a powerful burning-glass; and house furniture has been set on fire, by incautiously exposing it to the rays of the sun.

This invention may be considered as still in its infancy; but in the course of its improvement, its results may be highly beneficial and extensive. To use the words of Arago: "To copy the millions of millions of hieroglyphics, which entirely cover to the very exterior of the great monuments at Thebes, Memphis, Carnoc, etc., would require scores of years and legions of artists. With the Daguerreotype a single man would suffice to bring to a conclusion this vast labor; and at the same time, such designs shall incomparably surpass in fidelity, in truth of local color, the works of the ablest artists." It is probable, too, that this art may be applied to taking exact pictures of the heavenly bodies—not only of the sun, but even of the moon, the planets, and the stars. The plated discs prepared by Daguerre receive impressions from the action of the lunar rays to such an extent as permits the hope that photographic charts of the moon may soon be obtained. Nor is it perhaps too much to expect that the rays of the stars—even of distant nebulæ may thus be fixed and a delineation of their objects produced which shall be capable of being magnified by powerful microscopes.—This invention leads us to conclude that we have not yet discovered all the wonderful properties of that Light which unvails to us the beauties and sublimities of the universe; and that thousands of admirable agencies and objects hitherto unknown, may soon be disclosed to our view through this medium, as we advance in our researches and discoveries.

VI. Electricity.—This name has been given to a science which explains and illustrates the operations of a very subtile fluid, called the *electric fluid*, which appears to pervade every part of nature, and to be one of the chief agents employed in producing many of the phenomena of the material world. If a piece of amber, sealing-wax, or sulphur, be rubbed with a piece of flannel, it will acquire the power of attracting small bits of paper, feathers, or other light substances. If a tube of glass, two or three feet in length, and an inch or two in diameter, be rubbed pretty hard, in a dark room, with a piece of dry woolen cloth, beside attracting light substances, it will emit flashes of fire, attended with a crackling noise. This luminous matter is called electricity, or the *electric fluid*. If a large globe, or cylinder of glass, be turned rapidly round, and made to rub against a cushion, streams and large sparks of bluish flame will be elicited, which will fly round the glass, attract light bodies, and produce a pungent sensation, if the hand be held to it. This glass, with all its requisite apparatus, is called an *electrical machine*. It is found that this fluid will pass along some bodies, and not along others. The bodies over which it passes freely are water, and most other fluids, except oil and the aerial fluids; iron, copper, lead, and in general all the metals, semi-metals, and metallic ores; which are therefore called *conductors* of electricity. But it will not pass over glass, resin, wax, sulphur, silk, baked woods, or dry woolen substances; nor through air, except by force, *in sparks*, to short distances. These bodies are therefore called *non-conductors*.

The following facts, among others, have been ascertained respecting this wonderful agent:—That all bodies with which we are acquainted possess a greater or less share of this fluid—that the quantity usually belonging to any body produces no sensible effects; but when any surface becomes possessed of *more or less* than its natural share, it exhibits certain appearances in the form of light, sound, attraction, or repulsion, which are ascribed to the power called *electric*—that there are two different species of the electrical fluid, or at least two different modifications of the same general principle, termed *positive* and *negative* electricity—that positive and negative electricity always accompany each other; for if a substance acquire the one, the body with which it is rubbed acquires the other—that it moves with amazing rapidity, having been transmitted through wires of several miles in length, without taking up any sensible space of time; and therefore it is not improbable, that were an insulated conducting substance extended from one continent to another, it might be made to fly to the remotest regions of the earth in a few seconds of time*—that it has a power of suddenly contracting the muscles of animals, or of giving a *shock* to the animal frame—that this shock may be communicated, at the same instant, to a hundred persons, or to any indefinite number who form a circle, by joining their hands together—that it may be accumulated to such a degree as to kill the largest animals—that vivid sparks of this fluid, attended with a crackling noise, may be drawn from different parts of the human body, when the person is *insulated*, or stands upon a stool supported by glass feet—that electricity sets fire to gunpowder, spirits of wine, and other inflammable substances—that it melts iron wire and destroys the polarity of the magnetic needle—that it augments the natural evaporation of fluids, promotes the vegetation of plants, and increases the insensible perspiration of animals; and can be drawn from the clouds by means of electrical kites, and other elevated conductors. By means of the electrical power, small models of machinery have been set in action; orreries to represent the movements of the planets have been put in motion; and small bells have been set ringing for a length of time; and, in consequence of the knowledge we have acquired, of the mode of its operation in the system of nature, the lightnings of heaven have been arrested in their course, and constrained to descend to the earth, without producing any injurious effects.

From these, and a variety of other facts and experiments, it is now fully ascertained, that *lightning* and electricity are identical; and that it is the prime agent in producing the awful phenomena of a thunder-storm; the lightning being the rapid motion of vast masses of electric matter, and *thunder* the *noise*, with its echoes, produced by the rapid motion of the lightning through the atmosphere.—There can be little doubt that in combination with steam, the gases, and other agents, it also produces many of the terrific phenomena of earthquakes, volcanoes, whirlwinds, water-spouts, and hurricanes, and the sublime coruscations of the *aurora borealis*.—In the operations of this powerful fluid, we behold a striking display of the sovereignty and majestic agency of God. In directing its energies, "his way is in the whirlwind and the storm, and the clouds are the dust of his feet; the heavens are covered with sackcloth, the mountains quake before him, the hills melt, the earth is burned at his presence, and rocks are thrown down by him."* It is easy to conceive, that by a few slight modifications produced by the hand of Omnipotence, this powerful fluid might become the agent of producing either the most awful and tremendous, or the most glorious and transporting scenes, over every region of our globe. As it now operates, it is calculated to inspire us rather with awe and terror than with admiration and joy; and to lead our thoughts to a consideration of the state of man as a depraved intelligence, and a rebel against the government of his Maker.

---

* See Chap. III, Art. Electric Telegraph.

Electricity is rapidly extending its boundaries, and its influence as an important agent in the arts; and, as yet, we can form no adequate conception of the results which may flow from the investigations into its nature, combinations, and applications, which are now making by the scientific world, or of the powerful effects it may produce, when thoroughly wielded by the hand of genius. It has already been applied to many useful purposes—to remove obstructions in the human frame—to cure diseases—to ascertain the depths of the sea—to produce explosions for effecting mechanical operations,—and for conveying intelligence at the rate of 192,000 miles in a second. Among its recent applications is *the process of copying with perfect accuracy engraved copperplates, medals, seals, etc.*—and of gilding, plating, and etching, with great beauty and precision. This art has been denominated ELECTROTYPE, and was discovered by Mr. Thomas Spencer, of Liverpool, in 1839. It was also discovered on the Continent by Professor Jacobi. The materials recommended by him for forming the molds on which impressions are taken are *fusible metal*, *wax*, and *stearine*. When a copy is taken from any copperplate or medal, any number of copies can be produced equally as good as the first. The process is simple, but our limits will not permit to enter into its details. The reader will find a short description of the process in Chambers' "Information for the People," No. 57, Art. *Electricity, etc.*, and in the "Practical Mechanic and Engineer's Magazine," vol. i, p. 227.

An important combination of the Electrotype with the Daguerreotype process has lately been discovered, which promises to lead to some important results. A Daguerreotype picture can be produced in the ordinary way, as formerly described—it can be etched according to the present process, and from this etching an indefinite number of electrotype copies can be obtained. As an illustration of the perfection attendant on this process, the inventor states that, from a Daguerreotype plate which had on it a sign-board measuring 1–10th by 6–100ths of an inch, five lines of the inscription can be distinctly read by the aid of a microscope applied to the electrotype copy. So that, as the author remarks, "instead of a plate being inscribed as drawn by Landseer, and engraved by Cousins, it may be said, *drawn by Light and engraved by Electricity.*"

VII. GALVANISM is intimately connected with electricity, though it is generally considered as a branch of Chemistry. It is only another mode of exciting electrical action. In electricity the effects are produced chiefly by *mechanical* action; but the effects of Galvanism are produced by the *chemical* action of bodies upon each other. If we take a piece of zinc, and place it under the tongue, and lay a piece of silver, as big as a half-crown, above it; by bringing the outer edges of these pieces in contact, we shall immediately experience a peculiar and disagreeable taste, like that of copper. The same thing may be noticed with a guinea and a piece of charcoal. If a person, in the dark, put a slip of tinfoil upon one of his eyes, and a piece of silver in his mouth, by causing these pieces to communicate, a faint flash will appear before his eyes. If a living frog or a fish, having a slip of tinfoil pasted upon its back, be placed upon a piece of zinc, by forming a communication between the zinc and tinfoil, the spasms of the muscles are excited. These and similar effects are produced by that modification of electricity which has been termed *Galvanism.* Three different conductors, or what is called a *galvanic circle*, are requisite to produce such effects. A piece of copper, a piece of flannel, moistened with water or acid, and a piece of zinc, laid upon one another, form a circle; and if this circle be repeated a number of times, a galvanic pile or battery may be formed, capable of giving a powerful shock. The most common and convenient form, however, of a battery, is found to be a trough of baked wood, three or four inches deep, and as many wide. In the sides are grooves, opposite to each other, into each of which is placed a double metallic plate of zinc and copper soldered together, and the cells are then filled either with salt and water, or with a solution of nitrous acid and water.

By means of the galvanic agency, a variety of surprising effects have been produced. Gunpowder, cotton, and other inflammable substances have been inflamed—charcoal has been made to burn, with a most brilliant and beautiful white flame—water has been decomposed into its elementary parts—metals have been melted and set on fire—fragments of diamond, charcoal, and plumbago, have been dispersed, as if they had been evaporated—platina, the hardest and heaviest of the metals, has been melted as readily as wax in the flame of a candle—the sapphire, quartz, magnesia, lime, and the firmest compounds in nature, have been made to enter into fusion.—Its effects on the animal system are no less surprising. When applied to a fowl or a rabbit, immediately after life is extinct, it produces the most strange and violent convulsions on the nervous and muscular system, as if the vital functions were again revived: and when applied to the human body after death, the stimulus has produced the most horrible contortions and grimaces in the muscles of the head and face; and the most rapid movements in the hands and feet.

Numerous experiments which have been made both on dead animals and on human subjects, have led to the conclusion that galvanism possesses some *sanative* as well as energetic influence on the actions of diseased living beings. It has been found to effect cures, and to afford relief in nervous disorders. It has not only been used to cure the afflicted living, but also to resuscitate the apparently dead; and in all cases of suspended animation, from accidents or otherwise, it has been found to be a test of vitality, and the surest criterion of recent death. A celebrated medical writer on this subject, in Berlin, strongly recommends its use in rheumatism, palsies, nervous deafness, hoarseness, debility of sight, white swellings of the joints, tumors in the glands of the neck, and several other disorders. It is found that it possesses not only a stimulating power over the nerves and muscles, but also over the vital forces. M. Spronger, of Jena, gives an account of his having restored the sense of hearing to 45 persons, by means of this singular agent—to four of whom he also restored the sense of smelling.—Galvanism has been lately employed as a powerful agent for blasting rocks. At Glasgow, and several other places, its agency has been applied with great success. At one blast hundreds of tons of stones have been in a moment loosened from the rock. It is found that dry sand is quite sufficient for filling the perforation in the rock where the charge is placed, and that the whole process is unaccompanied with the smallest degree of danger, so that, by this mode of blasting, those accidents which have so frequently happened to workmen employed in such operations may be entirely prevented.

---

* Nahum, i. 3–6.

The galvanic agency enables us to account for the following, among other facts:—Why porter has a different and more pleasant taste when drunk out of a pewter vessel than out of glass or earthenware,—why a silver spoon is discolored when used in eating eggs,—why the limbs of people, under amputation, are sometimes convulsed by the application of the instruments,—why pure mercury is oxydized when amalgamated with tin,—why works of metal, which are soldered together, soon tarnish in the places where the metals are joined,—and why the copper sheathing of ships, when fastened with iron nails, is soon corroded about the place of contact. In all these cases a galvanic circle is formed which produces the effects. We have reason to believe that, in combination with the discoveries which modern chemistry is daily unfolding, the agencies of this fluid will enable us to carry the arts forward toward perfection, and to trace the secret causes of some of the sublimest phenomena of nature.

VIII. Magnetism.—This department of philosophy describes the phenomena and the properties of the *loadstone*, or natural magnet. The natural magnet is a hard dark-colored mineral body, and is usually found in iron mines. The following are some of its characteristic properties:—1. It attracts iron and steel, and all substances which contain iron in its metallic state. 2. If a magnet be suspended by a thread, or nicely poised on a pivot, or placed on a piece of wood, and set to float in a basin of water, one end will constantly point nearly toward the north pole of the earth, and the other toward the south; and hence, these parts of the magnet have been called the *north* and *south poles*. 3. When the north pole of one magnet is presented near to the south pole of another, they will *attract* each other; but if the north pole of one be presented to the north pole of another, or a south pole to a south, they will *repel* each other. 4. A magnet placed in such a manner as to be entirely at liberty, inclines one of its poles to the horizon, and of course elevates the other above it. This property is called the *dipping* of the magnet. 5. Magnets do not point directly north and south; but in different parts of the world with a different *declination* eastward or westward of the north: it is also different at the same place at different times. In London, and in most places of Great Britain, the magnetic needle in 1824 pointed about 24 degrees to the west of the north. For more than 160 years previously it had been gradually declining from the north to the west; but seemed then to have begun its declination to the eastward. 6. Any magnet may be made to communicate the properties now mentioned to any piece of iron or steel. For example, by gently rubbing a penknife with a magnet, it will be immediately invested with the property of attracting needles, or small pieces of iron or steel. 7. Heat weakens the power of a magnet, and the gradual addition of weight increases the magnetic power. 8. The properties of the magnet are not affected either by the presence or the absence of air; and the magnetic attraction is not in the least diminished by the interposition of any bodies except iron. A magnet will equally affect the needle of a pocket compass, when a thick board is placed between them, as when it is removed. It has been lately discovered, that the *violet rays of the solar spectrum*, when condensed with a convex glass, and made to pass along a piece of steel, have the power of communicating to it the magnetic virtue.

The cause which produces these singular properties of the magnet has hitherto remained a mystery; but the knowledge of the *polarity* of the magnet has been applied to a most important practical purpose. By means of it, man has now acquired the dominion of the ocean, and has learned to trace his course through the pathless deep to every region of the globe. There can be little doubt, that magnetism has an intimate connection with electricity, galvanism, light, heat, and chemical action; and the discoveries which have been already made, and others to be expected, from the experiments of Morichini, Oersted, Abraham, Hansteen, Barlow, Beaufoy, Ampère, and Scoresby, promise to throw some light on this mysterious agent, and on the phenomena of nature with which it is connected.

Electro-Magnetism.—This is a new science founded on the connection which is now ascertained to subsist between Electricity and Magnetism. In the year 1819, Professor Oersted of Copenhagen discovered that, when a wire conducting electricity is placed parallel to a magnetic needle, properly suspended, the needle will deviate from its original or natural direction. 1. If the needle be *above* the conducting wire, and the positive electricity goes from right to left, the *north* end of the needle will be moved *from* the observer, or to the *west*. 2. If the needle is *below* the wire, and the electricity passes as before, the *north* end of the needle will be moved *toward* the observer or to the *east*. 3. If the needle is in the same horizontal plane with the wire, and is between the observer and the wire, the *north* end of it will be *elevated*. 4. If the needle is similarly placed on the opposite side, the north end of it will be *depressed*. From these facts M. Oersted concludes, that the magnetical action of the electrical current has a circular motion round the wire which conducts it.—When these experiments were commenced, and repeated, and varied by other philosophers, a multitude of new facts were soon brought to light through the labors of Davy, Faraday, Ampère, Barlow, Biot, and other experimenters. Two very important facts were ascertained by Ampère and Davy—that the conjunctive wire itself becomes a magnet—and that magnetic properties might be communicated to a steel needle not previously possessing them, by placing it in an electrical current. The former of these facts is proved by throwing iron filings on paper and bringing them under the wire, when they will immediately adhere to it, forming a tuft round it 10 or 12 times the diameter of the wire. On breaking the connection with the battery, however, they immediately fall off, proving that the magnetic effect depends entirely on the passage of the electricity through the wire. The degree of force of the magnetic property thus communicated to the uniting wire, is considered by Sir H. Davy, to be proportional to the quantity of electricity transmitted through it Hence the finer the wire the more powerfully magnetic was it rendered; and hence also a battery of very large plates was found to give the strongest magnetism to the wire connecting its poles.

The following are some of the results of experiments which have been made on this subject;—1. The deviation of the magnetized needle is greater or less, according to the nature of the conducting wire; and copper appears to be of all metals that which produces the most powerful effects. 2. The intensity of an electrical current is constant throughout the whole of a homogeneous wire whatever may be its length. 3. If two homogeneous conductors be *simultaneously* adapted to the same galvantic pile—first, the absolute intensity of the current decreases in the inverse ratio of the square root of the length of the wire—and secondly, when the thickness of the wires is altered, the intensity of the current increases with their diameter to a certain limit, beyond which an increase of thickness no longer produces any change in the intensity of the current. 4. When the conjunctive wires of two distinct galvanic arrangements are made to approach each other, magnetic attractions and repulsions are observed. Two wires of copper, silver, or any other metal, connecting the extremities of two galvanic troughs, being placed parallel to each other, and suspended so as to move freely, immediately attract and repel each other, according as the directions of the currents of electricity flowing through them are the same or different.—On this experiment is founded the most plausible and rational theory of magnetism, namely, that *it arises from the attractions and repulsions of currents of electricity constantly circulating round every magnet.* This is considered as explaining the reason why the magnetic needle places itself at right angles to a wire conducting electricity, namely, that the electric current passing along the wire may coincide with that circulating round the magnet.

These, and a great number of other facts, it is presumed, clearly demonstrate the perfect resemblance, or rather identity, of electricity and magnetism. Magnetic phenomena are thus, in fact, a series of electrical phenomena, and magnetism may, with propriety, form a branch of electricity, under the head of *Electrical currents.* Currents of electricity, according to this theory, are essential to the production of magnetic phenomena; but these are not obvious in a common magnet. M. Ampère has suggested their existence, however, and has so arranged them theoretically, as to account for a great proportion of magnetic appearances. A magnet, he conceives, to be an assemblage of as many electrical currents moving round it in planes perpendicular to its axis, as there may be imagined lines, which, without cutting one another, form closed curves round it. A permanent magnet, then, may be conceived to be *a mass of iron or steel round the axis of which electric currents are continually circulating, and these currents attract all other electric currents flowing in the same direction, and repel all others which are moving in an opposite direction.* One important circumstance is always to be kept in view, that the electric currents flow round every magnet in the same direction in reference to its poles. If, for instance, we place a magnet with its north pole pointing to the north, in the usual position of the magnetic needle, the current of electricity flows round it from west to east—or in the direction in which the planets revolve, and the earth on its axis—or on the western side of the magnet it is moving upward, and on the eastern side downward; on the upper side from west to east, and on the lower side from east to west. This is ascertained to be a uniform law, and on these principles most of the phenomena of magnetism may be accounted for.

To complete the view of Ampère's doctrine on this point, it remains only to explain the influence of the earth on the magnet by which the needle is kept always in one position, nearly coinciding with the meridian. He maintains that currents of electricity, analogous to those which circulate round every magnet, are constantly floating round the globe, as the current of electricity in a galvanic apparatus moves in an unbroken circuit from the negative to the positive pole, and from it, by the connecting wire, round again to the negative pole. The direction of these currents he infers to be the same as has been stated with artificial magnets; and it is simply by the attractions and repulsions of these terrestrial currents, bringing the currents round the needle to coincide with them, that the latter always points to the north. The cause of these electric currents thus inferred to be constantly circulating round the globe, is, as yet, involved in obscurity. They are supposed to move at right angles to the magnetic meridian, or nearly parallel with the equator, on the eastern side of the earth moving from us, and on the western side flowing toward us. It is conjectured that the arrangement of the materials of the globe may be such as to constitute a battery, existing like a girdle round the earth, which, though composed of comparatively weak materials, may be sufficiently extensive to produce the effects of terrestrial magnetism. Its irregularity, and the changes it may accidentally or periodically suffer, may explain the phenomenon of the variation of the compass;—or the general action producing the currents of electricity may be affected by different causes, as the motions of the earth, the currents of the atmosphere, the process of evaporation, and the solar heat. It may also be supposed that much of the variation depends on the progress of oxydation in the continental regions of the globe.

In connection with the principles and phenomena stated above,—by means of a galvanic battery, *iron may be temporarily magnetized*—in other words, endowed with an attractive power, so long as it is kept in connection with the galvanic apparatus. A magnet of this kind is generally formed in the shape of a horse-shoe; and when suspended so as to present the extremities downward, and when the galvanic communication is established, the magnetic power is instantly exerted, and a bar of iron held to the extremities will be immediately attracted, and firmly adhere. But, on loosening the connection with the battery, the magnetic power is instantly destroyed, and the ball of iron falls to the ground. Such magnets, which have obtained the name of *Electro-magnets*, have been thus made, endowed with very great attractive power, so as to sustain, in some cases, a weight of above 2000 pounds, or nearly a ton. These magnets, like those which possess permanent magnetism, have opposite poles, one attracting, and the other repelling.

This new science of Electro-magnetism has opened up new and more expansive views to the philosophic world, in reference to the powers of Electricity, Galvanism, and Magnetism, and their relation to each other; and in the progress of the investigations which are now going forward, we have reason to hope that some of the hitherto latent principles which pervade our terrestrial system will be unfolded, and the diversified phenomena they produce more fully explained and illustrated. It is probable, too, that the arts will be improved by the application of the principles which this science has brought to light; and they have already been applied to machinery to produce rotatory and impulsive motions.

Such is a faint outline of some of the interesting subjects which Natural Philosophy embraces. Its relation to Religion will appear from the following considerations:—

1. Its researches have led to the invention of machines, engines, and instruments of various kinds, which augment the energies, increase the comforts, and promote the general improvement of mankind; and these objects are inseparably connected with the propagation of Christianity through the world. If we admit that, in future ages, the religion of the Bible will shed its benign influence over all nations—that the external condition of the human race will then be prosperous and greatly meliorated beyond what it has ever been—and, that no *miraculous interposition* of Deity is to be expected to bring about such desirable events—it will follow, that such objects can be accomplished only, in the ordinary course of Providence, by rational investigations into the principles and powers of Nature, and the application of the inventions of science to the great objects of religion, and of human improvement, as I shall endeavor briefly to illustrate in the following chapter. As the destructive effects of many physical agents, in the present constitution of our globe, are, doubtless, a consequence of the sin and depravity of man—we have reason to believe, that, when the economy of nature shall be more extensively and minutely investigated, and the minds of men directed to apply their discoveries to philanthropic and religious objects, they will be enabled to counteract, in a great measure, those devastations and fatal effects which are now produced by several of the powers of nature. The general happiness of all ranks, which will be connected with the universal extension of Christianity, necessarily supposes that this object will be accomplished; for, were a dread of destruction from the elements of nature frequently to agitate the mind, as at present, no permanent tranquillity would be enjoyed; nor would that ancient prediction in reference to this era, receive its full accomplishment, that "there shall be *nothing to hurt or destroy* in all God's holy mountain, when the earth shall be full of the knowledge of the Lord." And since miraculous interpositions are not to be expected, to what quarter can we look for those subordinate agencies by which this object is to be effected, but to the discoveries and inventions of philosophical science?

Science has already enabled us to remedy many of those evils which are the accidental effects of the operation of physical agents. For example—the discoveries of the philosopher, with respect to the nature of the electric fluid, have enabled us to construct conductors for preserving buildings from the stroke of *lightning;* and we have every reason to hope, that, in the progress of electric, galvanic, and chemical science, more complete thunder-guards, applicable to all the situations in which a person may be exposed, will be invented. Nay, our increasing knowledge of the electric fluid, and of the chemical agents which concur in its operation, may enable us to dissipate thunder-storms altogether, by disturbing the electricity of the clouds, by means of a series of elevated artificial conductors. This is not only possible, but has already been in some degree effected. The celebrated Euler informs us, in his "Letters to a German Princess," that he corresponded with a Moravian priest, named ***Divisch,*** who assured him, "that he had averted, during a whole summer, every thunder-storm which threatened his own habitation and the neighborhood, by means of a machine constructed on the principles of electricity—that the machinery sensibly attracted the clouds, and constrained them to descend quietly in a distillation, without any but a very distant thunderclap." Euler assures us, that "the fact is undoubted, and confirmed by irresistible proof." Yea, not only may the destructive effects of lightning be averted by the inventions of philosophy, but its agency may be rendered subservient to human industry, and made to act as a mechanical power. This effect, too, has been partially accomplished. About the year 1811, in the village of Philipsthal, in Eastern Prussia, an attempt was made to split an immense stone into a multitude of pieces, by means of lightning. A bar of iron, in the form of a conductor, was previously fixed to the stone, and the experiment was attended with the most complete success; for, during the very first thunder-storm, the lightning burst the stone without displacing it.*

It is, therefore, probable that, in the future ages of the world, this terrific meteor, and other destructive agents, which now produce so much alarm, and so many disastrous effects, may, by the aid of philosophy, be brought under the control of man, and be made to minister to his enjoyment.

The electric fluid has also been, in many instances, successfully applied in curing palsies, rheumatisms, spasms, obstructions, and inflammation; and it is known to have a peculiar effect on the nervous system. Lightning has been known to restore the blind to a temporary enjoyment of sight. Mr. Campbell, of Succouth, in Dunbartonshire, who had been blind for several years, was led by his servant one evening through the streets of Glasgow, during a terrible thunderstorm. The lightning sometimes fluttered along the streets for a quarter of a minute without ceasing. While this fluttering lasted, Mr. Campbell saw the street distinctly, and the changes which had been made in that part by taking down one of the city gates. When the storm was over, his entire blindness returned.—The following instance, stated by Professor Robison, as related by one of his friends, is no less remarkable. One evening in autumn, he was sitting with a gentleman who had the same disorder as the gentleman mentioned above, and he observed several lambent flashes of lightning. Their faces were turned to the parlor window; and immediately after a flash, the gentleman said to his wife, "Go, my dear, make them shut the white gate; it is open, you see." The lady did so, and returned; and, after a little, said, "But how did you know that the gate was open?" He exclaimed, with wonder, "I saw it open, and two men look in, and go away again"—which our friend also had observed—the gentleman, on being close-questioned, could not recollect having had another glance, nor why it had not surprised him; but of the glimpse itself he was certain, and described the appearance very exactly.†

It is also possible, that barren deserts might be enriched with fertility, and immense portions of the desolate wastes of our globe prepared for the support and accommodation of human beings, by arresting the clouds, and drawing down their electrical virtue and their watery treasure, by means of an extended series of elevated metallic conductors. What has been now stated, is only one instance out of many which might be produced, of the extensive and beneficial effects which may be produced, in future ages, by the application of the discoveries of natural science.

2. A knowledge of Natural Philosophy enables us to detect *pretended* miracles, and to discriminate between those phenomena which are produced by the powers of nature, and the supposed effects of diabolical influence. It has been chiefly owing to ignorance of the principles of natural science, that mankind, in all ages, have been so easily imposed upon by pretenders to supernatural powers. It is owing to the same cause, that superstitious notions and vain alarms have spread their influence so extensively among the lower ranks of the population of every country. The pretended miracles by which Pagan and Popish priests endeavor to support the authority of their respective religious systems, and every species of degrading superstition, vanish into smoke, when examined by the light of modern science; and there can be no question, that an enlightened Missionary would, in many instances, find the principles and the instruments of natural philosophy important auxiliaries in undermining the fabric of heathen idolatry and priestcraft. They tend to dissipate a thousand idle terrors which haunt and agitate the human mind; to detect a thousand kinds of imposture by which it has been held in cruel bondage; and to prevent the perpetration of those deeds of cruelty which have uniformly marked the reign of Superstition.[*] Had our forefathers connected a knowledge of this subject with their study of the Scriptures, they would not have brought upon themselves that indelible disgrace which now attaches to their memories, on account of their having condemned and burned at the stake thousands of unhappy women, accused of crimes of which they could not possibly have been guilty.[†] In New England, toward the close of the 17th century, the witchcraft frenzy rose so high, that the execution of witches became a calamity more dreadful than the sword or the pestilence. Not only old women, but children of ten years, were put to death; young girls were stripped naked, and the marks of witchcraft searched for upon their bodies with most indecent curiosity; and those spots of the scurvy which age impresses upon the bodies of old men were taken for evident signs of infernal power. So that ignorance of the laws and phenomena of nature has led even Christians to commit acts of injustice and horrid cruelty. For, let it be remembered that it was *Christian* magistrates and ministers, under a pretended zeal for the honor of God, who sanctioned such cruel and unrighteous decrees. This consideration, viewed in connection with many others, tends to show, that the Christian revelation, considered abstractly by itself, without a reference to the visible system of the universe, is not sufficient for all the purposes for which it was intended; as, on the other hand, the study of the works of nature is not sufficient of itself to lead the mind to the true knowledge of God, without the aid of the discoveries derived from the sacred oracles. For, although the Bible has been in the hands of Protestant Christians ever since the Reformation, yet it is only since the light of modern science began to diffuse its influence, that the superstitions of the dark ages, and the vulgar notions respecting witchcraft, necromancy, and other species of infernal agency, began to evanish, even from the minds of Christian teachers; as is evident from the writings of many eminent divines who flourished during the 16th and 17th centuries. As the two revelations which God has given throw a mutual luster on each other, the one must always be considered as incomplete without the other. Both are necessary, in order "to make the man of God perfect," and to enable him to prosecute, with intelligence and success, the great objects of religion; and the Christian minister who affects to despise the aids of science in the cause of religion has yet much to learn with respect to some of the grand bearings of the Christian system.

3. The investigations of natural philosophy *unfold to us the incessant agency of God*, and the plans by which his wise and benevolent designs in the system of nature are accomplished. From the immeasurable globes of heaven, down to the minutest atoms, we perceive a regular chain of causes and effects, conspiring, in a thousand different modes, to accomplish the purposes of infinite wisdom and goodness. The operation of central forces, and of the law of gravitation on the earth, and in the heavens—the hydrostatical laws which regulate the pressure and the motion of fluids—the chemical properties of the atmosphere, its undulatory, refractive, and reflective powers—the motion of the rays of light, and the infinite variety of effects they produce—the process of evaporation—the agencies of electricity and galvanism—the properties of the magnet, and the chemical action of acids and alkalies, and of the minutest particles of matter upon each other,—ought to be viewed as so many modifications of the agency of Deity, and as manifestations of his wisdom, in carrying forward those plans which regard the interests of his universal kingdom; just as we consider the rise and fall of empires, the revolutions of nations, and the circulation of the Scriptures in heathen lands, as so many acts of his moral administration as the Governor of mankind. For, let it be carefully remembered, that all these physical agencies have ultimately a moral and intellectual bearing; and are essentially connected with every other part of God's providential procedure. Though we may be apt to consider them as so many detached and insulated pieces of machinery, with which we have little concern, or may even disdain to notice their mode of operation; yet, in the all-comprehensive mind of Him who takes in, at one glance, the whole chain of causes and effects, they are as essentially con-

---

[*] Mr. Douglas, in his "Hints on Missions," suggests, that Natural Philosophy might be an important auxiliary to Christian Missionaries. "All the ancient 'war weapons of victory,' excepting miracles, are at their disposal; and new instruments of still greater potency, which the science of the latter days has been accumulating for universal revolution of the mind are ready to be brought into action, upon a scale of overpowering magnitude. Even the single resource which is lost may yet be recompensed by equivalents, and a substitute, in many respects, may be found for miracles. The first effect of a miracle is, to rouse the attention, and to overawe opposing prejudices; the second, to afford a proof of religion of which it is a sealing accompaniment.—*The first object might be gained by the natural magic of experimental philosophy;* and as to the second, the difference in the proof from miracles, lies rather in its being more circuitous, than in its being less conclusive at the present day, than in the times of the Apostles." Mr. Moffat, missionary from Africa, lately expressed to the author sentiments similar to the above, and intimated his ardent desire that he might be furnished, before his return, with an apparatus for the purpose of expanding the minds of heathen converts in the knowledge of nature.

[†] It has been calculated that, *in Germany alone*, the number of victims that suffered for the supposed crime of witchcraft from 1484—the date of the bull of Pope Innocent VIII, against witchcraft—until the beginning of the eighteenth century, considerably exceeds *one hundred thousand!*

nected with his ultimate purposes, and the eternal destiny of man, as are the revelations of his word.—Were a single principle or motion which now animates the system of nature to cease—were the agency of electricity, for example, or the principle of evaporation, to be destroyed—the physical constitution of our globe would instantly be deranged; nature would be thrown into confusion; and the sentient and intellectual beings that now inhabit the earth would either be destroyed, or plunged into an abyss of misery. If therefore we admit, that the *moral* agency of God is worthy of our contemplation, we ought to consider his physical operations also as no less worthy of our study and investigation; since they form the groundwork of all his other manifestations.

There is nothing, however, which so strikingly characterizes the bulk of mankind, and even the great mass of the Christian world, as that apathy and indifference with which they view the wonders of creation which surround them. They can look on all that is grand and beautiful and beneficent in nature, without feeling the least sentiment of admiration or of gratitude to that Being who is incessantly operating within them and around them; and they are disposed to consider the experiments of philosophers, by which the wonderful agency of God is unvailed, as only so many toys and amusements for the entertainment of children. They would prefer the paltry entertainments of a card-table, of a ball-room, or of a gossiping party, to the inspection of the nicest pieces of Divine mechanism, and to the contemplation of the most august scene in nature. However lightly some religionists may be disposed to treat this subject, that spirit of indifference with which the visible works of God are treated must be considered as flowing from the same *depraved principle*, which leads multitudes to reject the revelations of the Bible, and to trifle with their everlasting interests. "Man," says Rollin, "lives in the midst of a world of which he is the sovereign, as a stranger, who looks with indifference upon all that passes in it, and as if it were not his concern. The universe, in all its parts, declares and points out its Author; but, for the most part, to the deaf and blind, who have neither ears to hear, nor eyes to see. One of the greatest services that philosophy can do us, is to awaken us from this drowsiness, and rouse us from this lethargy, which is a dishonor to humanity, and in a manner reduces us below the beasts, whose stupidity is the consequence of their nature, and not the effect of neglect or indifference. It awakens our curiosity, it excites our attention, and leads us, as it were, by the hand, through all the parts of nature, to induce us to study and search out the wonderful works of it."*

Since, therefore, the science of natural philosophy is conversant about the works of the Almighty, and its investigations have a direct tendency to illustrate the perfections of his nature, to unvail the plan of his operations, to unfold the laws by which he governs the kingdom of universal nature, and to display the order, symmetry, and proportion, which reign throughout the whole—it would be needless to enter into any further process of reasoning, to show that the study of it is connected with the great objects of religion.—Whatever studies tend to raise our minds to the Supreme Ruler of all worlds—to expand our views of his infinite knowledge and wisdom—to excite our gratitude and our admiration of the beneficent designs which appear in all his arrangements—to guard us against erroneous conceptions of his providential procedure—and to furnish us with important auxiliaries for extending the influence of his religion through the world—must always be interesting to every Christian who wishes to enlarge his intellectual views, and to make progress in the knowledge of God.

CHEMISTRY.

This science, which is intimately related to the preceding, has for its object to ascertain the ingredients, or first principles, of which all matter is composed—to examine the compounds formed by the combination of these ingredients—to investigate those changes in natural bodies, which are not accompanied with *sensible* motion, and the nature of the power which produces these combinations and changes.

Within the limits of the last half century, the empire of Chemistry has been wonderfully extended. From an obscure and humble place among the objects of study, it has risen to a high and dignified station among those sciences which improve and adorn the human mind. No longer confined to the paltry and mercenary object of searching for the philosopher's stone, or of furnishing a little amusement, it now extends its sway over all the arts which minister to the comfort and improvement of social life, and over every species of animate and inanimate matter, within the range of human investigation. There is scarcely any science so immediately conducive to social improvement and human comfort. To whatever art or manufacture we turn our attention, we find that it has either been created by chemistry, or is indebted to its discoveries for some of its greatest improvements; and to whatever process in the material world we direct our investigations, the principles of this science, as deduced from modern experiments and discoveries, are capable of being applied. "The forms and appearances," says Sir Humphrey Davy, "of the beings and substances of the external world, are almost infinitely various, and they are in a state of continued alteration. Even the earth itself, throughout its whole surface, undergoes modifications. Acted on by moisture and air, it affords the food of plants; an immense number of vegetable productions arise from apparently the same materials; these become the substance of animals; one species of animal matter is converted into another; the most perfect and beautiful of the forms of organized life ultimately decay, and are resolved into inorganic aggregates; and the same elementary substances, differently arranged, are contained in the inert soil; or bloom, and emit fragrance in the flower; or become, in animals, the active organs of mind and intelligence. In artificial operations, changes of the same order occur: substances having the characters of earth, are converted into metals; clays and sands are united, so as to become porcelain; earths and alkalies are combined into glass; acrid and corrosive matters are formed from tasteless substances; colors are fixed upon stuffs; or changed, or made to disappear; and the productions of the vegetable, mineral, and animal kingdoms, are converted into new forms, and made subservient to the purposes of civilized life.—To trace, in detail, those diversified and complicated phenomena; to arrange them, and deduce general laws from their analogies, is the business of Chemistry."*

---

* Belles Lettres, vol. iv.

* Elements of Chemical Philosophy.

Chemists have arranged the *general forms of matter* into the four following classes:—The *first* class consists of SOLIDS, which form the principal parts of the globe, and which differ from each other in hardness, color, opacity, transparency, density, and other properties. The *second* class consists of fluids, such as water, oils, spirits, etc., whose parts possess freedom of motion, and require great mechanical force to make them occupy a smaller space. The *third* class comprehends ELASTIC FLUIDS, or GASES, which exist freely in the atmosphere; but may be confined by solids and fluids, and their properties examined. Their parts are highly movable, compressible, and expansive; they are all transparent; they present two or three varieties of color; and they differ greatly in density. The *fourth* class comprehends ETHEREAL SUBSTANCES, which are known to us only in their states of motion, when acting upon our organs of sense, and which are not susceptible of being confined. Such are the *rays of light*, and *radiant heat*, which are incessantly in motion, throughout the spaces that intervene between our globe, and the sun and the stars.—Chemists divide the substances in nature also into SIMPLE and COMPOUND. SIMPLE SUBSTANCES are those which have never yet been decomposed, nor formed by art. COMPOUND SUBSTANCES are those which are formed by the union of two or more simple substances. The following are all the *simple* substances with which we are at present acquainted: CALORIC, LIGHT, OXYGEN, NITROGEN, CARBON, HYDROGEN, SULPHUR, PHOSPHORUS, the METALS, and some of the EARTHS.—All that I propose under this article is simply to state some of the properties of two or three of these simple substances.

CALORIC, or elementary fire, is the name now given by chemists to that element or property which, combined with various bodies, produces the sensation of *heat* while it is passing from one body to another. This substance appears to pervade the whole system of nature. There are six different sources from whence Caloric may be procured. It may be produced by *combustion*, in which process the oxygen gas of the atmosphere is decomposed, and caloric, one of its component parts, set at liberty—by *friction*, or the rubbing of two substances against each other—by *percussion*, as the striking of steel against a piece of flint—by *the mixture of two or more substances*, as when sulphuric acid is poured upon water or magnesia—by *electricity and galvanism*. The discharge of an electric or galvanic battery, will produce a more intense degree of heat than any other means whatever. But the principal, and probably the original source of caloric, is the SUN, which furnishes the earth with a regular supply for the support and nourishment of the animal and vegetable tribes. From this source it moves at the rate of 192,000 miles in a second of time; for it has been already stated, that the sun sends forth rays of heat which are distinct from those which produce illumination, and which accompany them in their course through the ethereal regions.

Caloric is the cause of *fluidity*, in all substances which are capable of becoming fluid. A certain portion, or *dose* of it, reduces a solid body to the state of an incompressible fluid; a larger portion brings it to the state of an aeriform or gaseous fluid. Thus, a certain portion of caloric reduces ice to a state of water; a larger portion converts it into steam or vapor. There is reason to believe, that the hardest rocks, the densest metals, and every solid substance on the face of the earth, might be converted into a fluid, and even into a gas, were they submitted to the action of a very high temperature. This substance is called *sensible* caloric, when it produces the sensation of *heat;* and *latent* caloric, when it forms an insensible part of the substance of bodies. One of the principal effects of caloric is the *expansion* of bodies. All bodies, with a very few exceptions, are capable of expansion by means of heat; the gases being the most expansive, and solids the least susceptible of expansion. The expansion of gases or any aeriform substance is illustrated by the experiment of a half-blown bladder held before a fire, as stated under the article *Pneumatics*, p. 94. The expansion of solids is illustrated by the following process: When the iron rim of a cart-wheel is to be put on, it is first heated to a considerable degree. When hot, the circle is somewhat larger than when cold, and thus easily slips round the wheel; but, as it cools, the circle decreases, and firmly binds together the wood-work of which the wheel is composed. In reference to *fluid* bodies the same fact is exemplified in the *Thermometer*—the mercury or spirit of wine in which rises or falls in proportion to the quantity of heat which is applied to the instrument.—Other effects of heat are *liquefaction*, as when ice is converted into water—*vaporization*, as when water is converted into steam—*ignition*, as when bodies by heat are made to produce flame—and *evaporation*, when substances send off vapor from their surfaces at temperatures below the boiling point. The heat of the sun and other causes produce this effect every day over the whole surface of the globe. An immense quantity of vapor is thus continually rising from the surface of the land and seas, which is either formed into clouds, or condensed into rains or dew—which process is of most essential service throughout the whole economy of the physical constitution of our globe.—All bodies are, in a greater or less degree, *conductors* of caloric. Metals and liquids are good conductors of heat; but silk, cotton wool, wood, etc., are bad conductors of it. For example, if we put a short poker into the fire at one end, it will soon become hot at the other; but this will not happen with a piece of wood of the same length, and under the same circumstances. A person with a silken purse, containing metal coin, may stand so near the fire, as to make the metal almost too hot to touch, though the temperature of the purse will apparently be scarcely altered. If a hand be put upon a hot body, part of the caloric leaves the hot body and enters the hand, producing the sensation of heat. On the contrary, if a hand be put on a cold body, as a piece of iron, or another colder hand, part of the caloric contained in the hand leaves it to unite with the colder body, producing the sensation of cold. In short, caloric is diffused throughout all bodies, and enters into every operation in nature; and, were it not for the influence of this subtile fluid, there is reason to believe that the whole matter of the universe would be condensed into a solid mass.

OXYGEN is a very pure, subtile, and elastic substance, generally diffused throughout nature; but is never found unless in combination with other substances. It is one of the most important agents in nature; there being scarcely a single process, whether natural or artificial, in which oxygen has not some important share. When combined with caloric it is called *oxygen gas*, which forms one of the constituent parts of the atmosphere. It is a permanently elastic fluid, transparent, colorless, and destitute of taste and smell; 100 cubic inches of it weigh 33·9153 grains, that is, nearly 34 grains. And as the same bulk of common air weighs 30·8115 grains under the same circumstances, the specific gravity of oxygen is reckoned 1·1007, that of common air being reckoned 1·000, though some chemists have adopted 1·111 as its specific gravity compared with atmospheric air. In this state, it forms the principle of *combustion:* producing the most rapid deflagration of all combustible substances. If a lighted taper be let down into a jar of oxygen gas, it burns with such splendor that the eye can scarcely bear the glare of light, and at the same time produces a much greater heat than when burning in common air. If a steel wire, or a thin file, having a sharp point, armed with a piece of wood in inflammation, be introduced into a jar filled with this gas, the steel will take fire, and its combustion will continue producing a most brilliant phenomenon. It has been proved, by numerous experiments, that this gas is so *essential* to combustion, that no substance will burn in common air which has been previously deprived of its oxygen. It is also essential to the support of animal life; so that man, and all the inferior ranks of animated nature, may be said to depend upon this fluid for their existence. Its basis gives the *acid* character to all mineral and vegetable salts; and the *calcination* of metals is altogether effected by their union with oxygen. It constitutes the basis both of the atmosphere which surrounds the earth, and of the water which forms its rivers, seas, and oceans. It pervades the substance of all the vegetable tribes, and enables them to perform their functions; and, in combination with the different metals, serves the most important purposes in the useful arts. In the operation of this elementary principle, we perceive a striking display of the agency of the Creator, and of the admirable means which his wisdom has contrived for preserving in due order the system of nature. And as this wonderful substance is so essentially necessary to animal and vegetable existence, everything is so arranged as to produce a regular supply of it, notwithstanding its incessant changes, and the multifarious combinations into which it is continually entering.

One of the most extraordinary effects of oxygen appears, when it is combined, in a certain proportion, with nitrogen, so as to form the gaseous oxide of nitrogen, or what is commonly called *nitrous oxide.* This gas consists of 63 parts nitrogen, and 37 oxygen, by weight. When inhaled into the lungs, it produces an extraordinary elevation of the animal spirits, a propensity to leaping and running, involuntary fits of laughter, a rapid flow of vivid ideas, and a thousand delightful emotions, without being accompanied with any subsequent feelings of debility. This circumstance shows what a variety of delightful or pernicious effects might flow from the slightest change in the constitution of the atmosphere, were the hand of the Almighty to interpose in altering the proportion of its constituent parts; for atmospheric air is composed of 79 parts of nitrogen, and 21 of oxygen, which is not a very different proportion from the above. Another gas, called *nitric* oxide, composed of 56 parts oxygen, and 44 nitrogen, produces instant suffocation in all animals that attempt to breathe it. One of the most corrosive acids, the *nitrous* acid, or aquafortis, is composed of 75 parts oxygen, and 25 parts nitrogen; so that we are every moment breathing a certain substance, which, in another combination, would produce the most dreadful pain, and cause our immediate destruction. What a striking proof does this afford of the infinite comprehension of the Divine Mind, in foreseeing all the consequences of the elements of nature, and in directing their numerous combinations in such a manner as to promote the happiness of animated beings!

NITROGEN, or *azote,* is a substance generally diffused throughout nature, and particularly in animal bodies. It is not to be found in a solid or liquid state, but, combined with caloric, it forms *nitrogen gas,* which is one of the ingredients of the atmosphere. It enters extensively into combination with various substances; it is an abundant element in animal matter; and its existence in such large quantity is a chief distinction between the constitution of the substances which compose animal and vegetable matter. Its specific gravity is 0·9748, which is lighter than common atmospheric air, and therefore ascends in it. Were it heavier it would accumulate to such a degree in our apartments as to be pernicious and even destructive to our health and existence. It is incapable of supporting either flame or animal life. This is proved by introducing an animal, or a burning candle, into a vessel full of this gas; in which case, the animal is suddenly suffocated, and the candle instantly extinguished. It is this gas which is expelled from the lungs at every expiration, and rising over our heads, soon enters into new combinations. Though it is destructive to animal life, it appears to be favorable to plants, which vegetate freely when surrounded with nitrogen.

HYDROGEN is another elementary substance, abundant in nature, and, when united to caloric, forms *hydrogen gas.* It is one of the constituent parts of *water;* for it has been completely demonstrated by experiment, that water is composed of 85 parts by weight of oxygen, and 15 of hydrogen, in every hundred parts of the fluid. This gas was formerly known by the name of *inflammable air.* It is distinguished among miners by the name of *fire-damp;* it abounds in coal-mines, and sometimes produces the most tremendous explosions.* It is incapable by itself of supporting combustion, and cannot be breathed without the most imminent danger. It is the chief constituent of oils, fats, spirits, ether, coals, and bitumen; and is supposed to be one of the agents which produce the *ignes fatui,* and the *northern lights.* It is the *lightest* of all ponderable bodies, being from twelve to fifteen times lighter than common air A hundred cubic inches of it weigh about 2¼ grains. On account of its great levity, it is used for filling *air balloons.* In contact with atmospheric air, it burns with a pale blue color. When mixed with oxygen gas, it may be exploded, like gunpowder, with a violent report. *Carburetted hydrogen gas,* which is *carbon* dissolved by hydrogen, is that beautiful gas which is now employed in lighting our streets, shops, and manufactories.

---

* It appears from the First Report of the "Children's Employment Commission," appointed by Parliament in 1842, that, *at the very least,* 1500 lives have been sacrificed in and about the Tyne and Weir collieries in the neighborhood of Newcastle within the last 40 years, chiefly by the explosions of hydrogen gas which have taken place in the coal-mines. To counteract such effects, Sir H. Davy, in 1815, displayed his ingenuity by the invention of his *Safety Lamp*—which is made of wire gauze, and has this particular property, that the miner may move about with it, and even work by its light in the midst of those explosive mixtures which have so often proved fatal, when entered with a common lamp or candle. But the want of accuracy in some of the manufacturers of the gauze with which the instrument is constructed—and the carelessness of the miners in using it—have frequently prevented its beneficial effects from being realized. For a particular description of this lamp, see "Diffusion of Knowledge," Secs. II, V, and the Appendix.

CARBON is another simple substance extensively diffused throughout nature. It is found pure and solid only in the *diamond;* but it may be procured in the state of *charcoal*, by burning a piece of wood, closely covered with sand, in a crucible. Carbon enters into the composition of bitumen and pit coal, and of most animal and some mineral substances; and it forms nearly the whole of the solid basis of all vegetables, from the most delicate flower to the stately oak. It is also a component part of sugar, and of all kinds of wax, oils, gums, and resins. It combines with iron in various proportions, and the results are, cast-iron and steel. Black lead is a composition of nine parts of carbon to one of iron; and is therefore called a *carburet* of iron. Carbon is *indestructible* by age, and preserves its identity in all the combinations into which it enters—*Carbonic acid gas* is a combination of carbon and oxygen. It is found in a state of combination with lime, forming limestone, marble, and chalk; and may be separated from them by heat, or by means of the mineral acids. This gas, which was formerly called *fixed air*, is found in mines, caves, the bottoms of wells, wine cellars, brewers' vats, and in the neighborhood of limekilns. It is known to miners by the name of *choke-damp*, and too frequently runs on deadly errands. It extinguishes flame and animal life. It is the heaviest of all the gases; being nearly twice the weight of common air, and twenty times the weight of hydrogen. It may therefore be poured from one vessel to another; and a lighted taper is instantly extinguished by pouring a small quantity of it over the flame. It is a powerful *antiseptic*, or preserver from putrefaction. Meat which has been sealed up in it (says Mr. Parkes), has been known to have preserved its texture and appearance for more than twenty years. There is no substance of more importance in civilized life than the different forms of *Carbon.* "In nature," says Sir H. Davy, "this element is constantly active in an important series of operations. It is evolved in fermentation and combustion, in Carbonic acid; it is separated from oxygen in the organs of plants; it is a principal element in animal structures; and is found in different forms in almost all the products of organized beings."

CHLORINE is a gas of a greenish color. It is fatal to animal life, if breathed undiluted with common air, but it does not, like nitrogen and carbonic acid gas, extinguish combustion. A candle burns in it with a red flame; and it possesses the remarkable property of setting fire to many of the metals, even at the common temperature of the air, when introduced into it beaten out into thin leaves or reduced to filings—such as copper, tin, arsenic, zinc, and antimony. It has the property of destroying all vegetable colors. If a vegetable *blue*, for instance, be exposed to its action, the color is not changed to a *red*, as it would be by an acid,—nor to a green, as it would be by an alkali,—but it is totally destroyed. On this account Chlorine has been introduced as a powerful agent in the art of bleaching; for if unbleached linens be properly exposed to its action, the matter which gives them their gray color is destroyed. But if applied in its pure state, and not sufficiently diluted, it invariably destroys the strength and texture of the linens. The specific gravity of this gas, when free from watery vapor is 2·5, common air being 1· and 100 cubic inches of it weigh about 77 grains.

IODINE is the name of an undecompounded principle or element in chemistry. It remained undiscovered until 1812, when a manufacturer of saltpeter in Paris detected it in the ashes of sea weeds. It resembles chlorine in some of its properties, and is derived from a source which also supplies chlorine, both of them being of marine origin. It may be procured by drying and powdering common sea weed, and heating it with sulphuric acid. A *violet*-colored vapor rises, which, if received in a cool vessel, will condense on its sides, and will form scaly crystals of a somewhat metallic luster. These crystals are the substance in question; and from the violet color of its vapor it is called *iodine.* Its specific gravity is 3·084; it melts at a heat a little above that of boiling water; at the temperature of 350° it boils and evaporates in a violet-colored vapor. It stains the fingers yellow, and consumes the cork of the vial in which it is contained. Its smell is disagreeable, its taste acrid, it destroys vegetable colors, and it possesses poisonous properties. It has the property of forming a beautiful blue color, when mixed with a little powdered starch, and diffused through cold water; and hence iodine and starch are used by chemists as mutual tests of each other's presence, even in the most minute quantity.

SULPHUR is a substance which has been known from the earliest ages. It was used by the ancients in medicine, and its fumes have, for more than 2000 years, been employed in bleaching wool. It is found combined with many mineral substances, as arsenic, antimony, copper, and most of the metallic ores. It exists in many mineral waters, and in combination with vegetable and animal matters, but is most abundant in volcanic countries, particularly in the neighborhood of Vesuvius, Etna, and Hecla in Iceland. It is a solid, opaque, combustible substance, of a pale yellow color, very brittle, and almost without taste or smell. Its specific gravity is nearly twice that of water: it is a non-conductor of electricity, and, of course, becomes electric by friction. When heated to the temperature of 170° of Fahrenheit's thermometer, it rises up in the form of a fine powder, which is easily collected in a proper vessel, and is named the *flowers of sulphur.* It is insoluble in water, but may be dissolved in oils, in spirit of wine, and in hydrogen gas. When sulphur is heated to the temperature of 302° in the open air, it takes fire spontaneously and burns with a pale blue flame, and emits a great quantity of fumes of a strong suffocating odor. When heated to the temperature of 570°, it burns with a bright white flame, and emits a vast quantity of fumes. When these fumes are collected, they are found to consist entirely of *sulphuric acid;* so that sulphur, by combustion, is converted into an *acid.* It is the base of several compound substances. It unites with oxygen, hydrogen, nitrogen, phosphorus, the alkalies, the metals, and some of the earths. This substance is of great importance in medicine, as it is found to penetrate to the extremities of the most minute vessels, and to impregnate all the secretions. It is also used in the arts, particularly in bleaching and dyeing; it forms a very large proportion of gunpowder; and one of its most common but not least useful properties, is that of its *combustibility*, by which, with the help of a tinder-box, light is almost instantaneously produced. As this substance has not yet been decomposed, it is considered by chemists, in the meantime, as one of the simple substances.

PHOSPHORUS is another simple combustible substance, but is never found in a pure state in nature. It is commonly united to oxygen in the state of phosphoric acid, which is found in different animal, vegetable, and mineral substances. It was first discovered by Brandt, a chemist of Hamburgh, in the year 1667, and afterward by the Honorable Mr. Boyle, in 1679. It was formerly obtained by a disgusting process; but is now extracted from the bones of animals, by burning them, and then reducing them to a fine powder, and afterward pouring sulphuric acid upon them. This substance, when pure, resembles bees' wax, being of a clear, transparent, yellowish color; it is insoluble in water; it may be cut with a knife, or twisted to pieces with the fingers; and it is about double the specific gravity of water. Its most remarkable property is its very strong attraction for oxygen, from which circumstance it burns spontaneously in the open air at the temperature of 43°; that is, it attracts the oxygen gas from the atmosphere, and heat and flame are produced. It gradually consumes when exposed to the common temperature of air, emits a whitish smoke, and is luminous in the dark; for this reason it is kept in vials of water; and as the heat of the hand is sufficient to inflame it, it should seldom be handled except under water. At the temperature of 99° it melts; it evaporates at 219°, and boils at 554°. When heated to 148° it takes fire, and burns with a very bright flame, and gives out a large quantity of white smoke, which is luminous in the dark: at the same time it emits an odor, which has some resemblance to that of garlic; and this smoke, when collected, is proved to be an *acid*. It burns with the greatest splendor in oxygen gas, and, when taken internally, it is found to be poisonous. If any light substance, capable of conducting heat, be placed upon the surface of boiling water, and a bit of phosphorus be laid upon it, the heat of the water will be sufficient to set the phosphorus on fire. If we write a few words on paper, with a bit of phosphorus fixed in a quill, when the writing is carried into a dark room it will appear beautifully luminous. If a piece of phosphorus, about the size of a pea, be dropped into a tumbler of hot water, and a stream of oxygen gas forced directly upon it, it will under water display the most brilliant combustion that can be imagined. All experiments with phosphorus, however, require to be performed with *great caution*. This substance is used in making phosphoric match-bottles, phosphoric oil, phosphoric tapers, and various phosphoric fire-works. *Phosphorized hydrogen gas* is produced by bits of phosphorus remaining some hours in hydrogen gas. It is supposed to be that gas which is seen hovering on the surface of burial-grounds and marshes, known in Scotland by the name of *spunkie*, and in England by that of *will-o'-the-wisp*.

Some animals, as the *glow-worm* and the *fire-fly*, and fish in a putrescent state, exhibit phosphorescent qualities. M. Peron describes a singular instance of this kind in an animal which he calls the *pyrosoma atlanticum*, which he observed in his voyage from Europe to the Isle of France. The darkness was intense when it was first discovered; and all at once there appeared at some distance, as it were, a vast sheet of phosphorus floating on the waves, which occupied a great space before the vessel. When the vessel had passed through this inflamed part of the sea, it was found, that this prodigious light was occasioned by an immense number of small animals, which swam at different depths, and appeared to assume various forms. Those which were deepest looked like great red-hot cannon balls, while those on the surface resembled cylinders of red-hot iron. Some of them were caught, and were found to vary in size from three to seven inches. All the exterior surface of the animal was bristled with thick oblong tubercles, shining like so many diamonds; and these seemed to be the principal seat of its wonderful phosphorescence.

Such is a brief description of the principal elementary substances, which, in a thousand diversified forms, pervade the system of nature, and produce all that variety which we behold in the atmosphere, the waters, the earth, and the various processes of the arts. It is probable that some of these substances are compounds, though they have not yet been decomposed. Yea, it is possible, and not at all improbable, that there are but two, or at most three elementary substances in nature, the various modifications of which produce all the beauties and sublimities in the universe. Perhaps caloric, oxygen, and hydrogen, may ultimately be found to constitute all the elementary principles of nature.—Without prosecuting this subject further, I shall conclude this article with a few cursory reflections, tending to illustrate its connection with religion.

The remarks which I have already thrown out in reference to Natural Philosophy will equally apply to the science of Chemistry; and therefore do not require to be repeated. In addition to these, the following observations may be stated:—

1. This science displays, in a striking point of view, the wisdom and goodness of God, in *producing, by the most simple means, the most astonishing and benevolent effects*. All the varied phenomena we perceive throughout the whole system of sublunary nature are produced by a combination of six or seven simple substances. I formerly adverted to the infinite variety which exists in the vegetable kingdom.* About 56,000 different species of plants have already been discovered by botanists. All these, from the humble shrub to the cedar of Lebanon, which adorn the surface of the globe, in every clime, with such a diversity of forms, shades, and colors, are the result of the combinations of "four or five natural substances —caloric, light, water, air, and carbon." "When we consider," says Mr. Parkes, "that the many thousand tribes of vegetables are not only all formed from a few simple substances, but that they all enjoy the same sun, vegetate in the same medium, and are supplied with the same nutriment, we cannot but be struck with the rich economy of nature, and are almost induced to doubt the evidence of those senses with which the God of nature has furnished us. That it should be possible so to modify and intermingle a few simple substances, and thence produce all the variety of form, color, odor, etc., which is observable in the different families of vegetables, is a phenomenon too astonishing for our comprehension.—Nothing short of Omnipotence could have provided such a paradise for man."†

> "Soft roll your incense, herbs and fruits and flowers,
> In mingled clouds, to Him whose sun exalts,
> Whose breath perfumes you, and whose pencil paints."
> THOMSON.

What an admirable view is here opened up of the economy of Divine wisdom, and of the beneficent care which has been taken to secure the comfort and happiness of every living creature; and how ungrateful a disposition must it indicate in rational beings to overlook such benevolent arrangements! It is highly probable, that, in all the other worlds dispersed throughout the universe, an infinite diversity of scenery exists, and that no one globe or system exactly resembles another; and yet it is probable, that the primary elements of matter, or the few *simple substances* of which our world is composed, may be of the same nature as those which form the constituent parts of every other system; and may give birth to all the variety which exists throughout the wide extent of creation, and to all the changes and revolutions through which the different systems may pass, during every period of infinite duration.

---

* See p. 34.

† Chemical Catechism, chap. ix.

2. From this science we have every reason to conclude that matter is indestructible. In the various changes that take place in material substances, the particles of matter are not destroyed, but only assume new forms, and enter into new combinations. When a piece of wood, for example, is burned to ashes, none of its principles are destroyed; the elementary substances of which it was composed are only separated from one another, and formed into new compounds. Carbon, as already stated, appears to be indestructible by age, and to preserve its essential properties, in every mode of its existence. That Being, indeed, who created matter at first, may reduce it to nothing when he pleases; but it is highly improbable that his power will ever be interposed to produce this effect; or that any particle of matter which now exists, will ever be annihilated, into whatever new or varied combinations it may enter. When any particular world, or assemblage of material existence, has remained in its original state for a certain period of duration, and accomplished all the ends it was intended to subserve in that state, the materials of which it is composed will, in all probability, be employed for erecting a new system, and establishing a new series of events, in which new scenes, and new beauties and sublimities will arise from new and varied combinations. For the Creator does nothing in vain. But to annihilate, and again to create, would be operating in vain; and we uniformly find, that in all the arrangements of Deity, in the present state of things, Nature is frugal and economical in all her proceedings; so that there is no process, when thoroughly investigated, that appears unnecessary or superfluous.

From the fact, that matter appears to be indestructible, we may learn, that the Creator, with the self-same materials which now exist around us, may, after the general conflagration, new-model and arrange the globe we inhabit, so as to make a more glorious world to rise out of its ashes; purified from those physical evils which now exist; and fitted for the accommodation either of renovated men, or of other pure intelligences. From the same fact combined with the consideration of the infinite diversity of effects which the simple substances of nature are capable of producing, we may be enabled to form a conception of the ease with which the Creator may new-model our bodies, after they have been dissolved in the dust; and how, from the same original atoms, he may construct and adorn them with more glorious forms, and more delightful and exquisite senses than they now possess.

In short, the rapid progress which chemical science is now making, promises, ere long, to introduce improvements among the human race, which will expand their views of the agency of God, counteract many physical evils, and promote, to an extent which has never yet been experienced, their social and domestic enjoyment.—The late discoveries of Chemistry tend to convince us, that the properties and powers of natural substances are only beginning to be discovered. Who could have imagined, a century ago, that an invisible substance is contained in a piece of coal, capable of producing the most beautiful and splendid illumination—that this substance may be conveyed, in a few moments, through pipes of several miles in length—and that a city, containing several hundred thousands of inhabitants, may be instantly lighted up by it, without the aid of either wax, oil, or tallow? Who could have imagined that one of the ingredients of the air we breathe is the principle of combustion—that a rod of iron may be made to burn in it with a brilliancy that dazzles the eyes—that a piece of charcoal may be made to burn with a white and splendid light, which is inferior only to the solar rays—and that the *diamond* is nothing more than *carbon* in a crystallized state, and differs only in a slight degree from a bit of common charcoal?—Who could have surmised, that a substance would be discovered, of such a degree of levity, as would have power sufficient to buoy up a number of men to the upper parts of the atmosphere, and enable them to swim, in safety, above the region of the clouds? These are only specimens of still more brilliant discoveries which will, doubtless, be brought to light by the researches of future generations. We have reason to believe, that the investigations of this science will in due time, enable us to counteract most of the diseases incident to the human frame; and to prevent many of those fatal accidents to which mankind are now exposed. Davy's *safety lamp* has already preserved many individuals from destruction, when working in coal mines; and thousands, in after ages, will be indebted to this discovery, for security from the dreadful explosions of hydrogen gas. And, we trust, that the period is not far distant, when specific antidotes to the diseases peculiar to the different trades and occupations in which mankind are employed will be discovered; and the health and vigor of the mass of society be preserved unimpaired, amidst all the processes in which they may be engaged.

In fine, the rapid progress of chemical discovery carries forward our views to a period, when man, having thoroughly explored the powers of nature, and subjected them, in some measure, to his control, will be enabled to ward off most of those physical evils with which he is now annoyed, and to raise himself, in some degree, to the dignity and happiness he enjoyed before moral evil had shed its baleful influence on our terrestrial system. Such a period corresponds to many of the descriptions contained in the Sacred Oracles of the millennial state of the church; when social, domestic, moral, and intellectual improvement shall be carried to the utmost perfection which our sublunary station will permit; when wars shall cease; when the knowledge of Jehovah shall cover the earth; when every man shall sit under his vine and fig-tree, without being exposed to the least alarm; and when there shall be no thing to hurt nor destroy throughout the church of the living God. And, therefore, we ought to consider the various discoveries and improvements now going forward in this, and other departments of science, as preparing the way for the introduction of this long-expected and auspicious era.

ANATOMY AND PHYSIOLOGY.

The general object of both these sciences is, to investigate and describe the structure and economy of the animal frame.—*Anatomy* dissects *dead* bodies. *Physiology* investigates the functions of those that are *living*. The former examines the fluids, muscles, viscera, and all the other parts of the human body, in a state of *rest;* the latter considers them in a state of *action*.

The parts of the human body have been distinguished into two different kinds—solids and fluids. The solid parts are, *bones, cartilages, ligaments, muscles, tendons, membranes, nerves, arteries, veins, hair, nails,* and *ducts,* or fine tubular vessels of various kinds. Of these solid parts, the following compound organs consist: the *brain* and *cerebellum,* the *lungs,* the *heart,* the *stomach,* the *liver,* the *spleen,* the *pancreas,* the *glands,* the *kidneys,* the *intestines,* the *mesentery,* the *larynx,* and the organs of sense—the *eyes, ears, nose,* and *tongue.* The fluid parts are, the *saliva,* or spittle, *phlegm, serum,* the *chyle, blood, bile, milk, lympha, urine,* the *pancreatic juice,* and the *aqueous humor* of the eyes. The human body is divided into three great cavities—the *head;* the *thorax,* or breast; and the *abdomen,* or belly. The *head* is formed of the bones of the cranium, and incloses the brain and cerebellum. The *thorax* is composed of the vertebræ of the back, the sternum, and true ribs; and contains the *heart,* the *pericardium,* the *breasts,* and the *lungs.* The *abdomen* is separated from the thorax by means of the *diaphragm,* which is a fleshy and membranous substance, composed for the most part of muscular fibers. This cavity is formed by the lumbar vertebræ, the os sacrum, the ossa innominata, the false ribs, the peritoneum, and a variety of muscles. It incloses the stomach, intestines, omentum, or caul, the liver, pancreas, spleen, kidneys, and urinary bladder.—Without attempting any technical description of these different parts, which could convey no accurate ideas to a general reader, I shall merely state two or three facts in relation to the system of bones, muscles, and blood-vessels, as *specimens* of the wonderful structure of our bodily frame.

The BONES may be regarded as the propwork or basis on which the human body is constructed. They bear the same relation to the animal system, as the woodwork to a building. They give shape and firmness to the body; they support its various parts, and prevent it from sinking by its own weight; they serve as levers for the muscles to act upon, and to defend the brain, the heart, the lungs, and other vital parts from external injury. Of the bones, some are *hollow,* and filled with marrow; others are *solid* throughout; some are very *small;* others very *large;* some are *round,* and others *flat;* some are *plane,* and others *convex* or *concave;*—and all these several forms are requisite for the situations they occupy, and the respective functions they have to perform.—The *spine,* or back-bone, consists of 24 vertebræ, or small bones, connected together by cartilages, articulations, and ligaments; of which 7 belong to the neck, 12 to the back, and 5 to the loins. In the center of each vertebra, there is a hole for the lodgment and continuation of the spinal marrow, which extends from the brain to the rump. From these vertebræ the arched bones called *ribs* proceed; and seven of them join the breast-bone on each side, where they terminate in cartilages, and form the cavity of the thorax or chest. The five lower ribs, with a number of muscles, form the cavity of the abdomen, as above stated. The spine is one of the most admirable mechanical contrivances in the human frame. Had it consisted of only three or four bones, or had the holes in each bone not exactly corresponded, and fitted into each other, the spinal marrow would have been bruised, and life endangered at every bending of the body. The skull is composed of 10 bones, and about 51 are reckoned to belong to the face, the orbits of the eyes, and the jaws in which the teeth are fixed. There are seldom more than 16 teeth in each jaw, or 32 in all.—The number of bones in a human body is generally estimated at about 245; of which there are reckoned, in the skull, head, and face, 61; in the trunk, 64; in the arms and hands, 60; and in the legs and feet, 60. The bones are provided with *ligaments*, or hinges, which bind and fasten them together, and prevent them from being displaced by any violent motion; and, that the ligaments may work smoothly into one another, the joints are separated by *cartilages,* or gristles, and provided with a gland for the secretion of oil, or *mucus,* which is constantly exuding into the joints; so that every requisite is provided by our Benevolent Creator, to prevent pain, and to promote facility of motion. "In considering the joints," says Dr. Paley, "there is nothing, perhaps, which ought to move our gratitude more than the reflection, *how well they wear.* A limb shall swing upon its hinge, or play in its socket, many hundred times in an hour, for sixty years together, without diminution of agility; which is a long time for anything to last, for anything so much worked as the joints are."

The MUSCULAR SYSTEM.—A *muscle* is a bundle of fleshy, and sometimes of tendinous fibers. The fleshy fibers compose the body of the muscle; and the tendinous fibers the extremities. Some muscles are long and round; some plain and circular; some have *spiral,* and some have *straight* fibers. Some are double, having a tendon running through the body from head to tail; some have two or more tendinous branches running through, with various rows and orders of fibers. All these, and several other varieties, are essentially requisite for the respective offices they have to perform in the animal system. The muscles constitute the fleshy part of the human body, and give it that varied and beautiful form we observe over all its surface. But their principal design is, to serve as *the organs of motion.* They are inserted, by strong tendinous extremities, into the different bones of which the skeleton is composed; and by their contraction and distention, give rise to all the movements of the body. The muscles, therefore, may be considered as so many cords attached to the bones; and the Author of Nature has fixed them according to the most perfect principles of mechanism, so as to produce the fittest motions in the parts for the movements of which they are intended.

One of the most wonderful properties of the muscles is, the *extraordinary force they exert,* although they are composed of such slender threads, or fibers. The following facts in relation to this point, are demonstrated by the celebrated *Borelli,* in his work, *"De Motu Animalium."* When a man lifts up with his teeth a weight of 200 pounds with a rope fastened to the jaw-teeth, the muscles named *Temporalis* and *Masseter,* with which people chew, and which perform this work, exert a force of above 15,000 pounds weight. If any one hanging his arm directly downward, lifts a weight of 20 pounds, with the third or last joint of his thumb, the muscle which bends the thumb, and bears that weight, exerts a force of about *three thousand pounds.* When a man, standing upon his feet, leaps or springs upward to the hight of two feet, if the weight of such a man be 150 pounds, the muscles employed in that action will exert a force 2000 times greater; that is to say, a force of about *three hundred thousand pounds* The *heart,* at each pulse or contraction, by which it protrudes the blood out of the arteries into the veins, exerts a force of above *a hundred thousand pounds.* Who can contemplate this amazing strength of the muscular system, without admiration of the power and wisdom of the Creator, who has indued a bundle of threads, each of them smaller than a hair, with such an astonishing degree of mechanical force! There have been reckoned about 446 muscles in the human body, which have been dissected and distinctly described; every one of which is essential to the performance of some one motion or other, which contributes to our ease and enjoyment; and, in most instances, a great number of them is required to perform their different functions at the same time. It has been calculated, that about *a hundred muscles* are employed every time we breathe.—"Breathing with ease," says Dr. Paley, "is a blessing of every moment; yet, of all others, it is that which we possess with the least consciousness. A man in an asthma is the only man who knows how to estimate it."

The HEART and BLOOD-VESSELS.—The heart is a hollow muscular organ, of a conical shape, and consists of four distinct cavities. The two largest are called *ventricles*, and the two smallest *auricles.* The ventricles *send out* the blood to the arteries; the auricles *receive* it from the veins. The heart is inclosed in the *pericardium*, a membranous bag, which contains a quantity of water or lymph. This water lubricates the heart, and facilitates all its motions. The heart is the general reservoir of the blood. When the heart contracts, the blood is propelled from the *right ventricle* into the lungs, through the pulmonary arteries, which, like all the other arteries, are furnished with *valves* that play easily forward, but admit not the blood to return toward the heart. The blood, after circulating through the lungs, and having there been revivified by coming in contact with the air, and imbibing a portion of its oxygen, returns into the *left auricle* of the heart, by the pulmonary vein. At the same instant, the *left ventricle* drives the blood into the *aorta*, a large artery which sends off branches to supply the head and arms. Another large branch of the aorta descends along the inside of the backbone, and detaches numerous ramifications to nourish the bowels and inferior extremities. After serving the most remote extremities of the body, the arteries are converted into *veins*, which, in their return to the heart, gradually unite into larger branches, until the whole terminate in one great trunk, called the *vena cava*, which discharges itself into the *right auricle* of the heart, and completes the circulation. Each ventricle of the heart is reckoned to contain about one ounce, or two table spoonsful of blood. The heart contracts 4000 times every hour; and, consequently, there passes through it 250 pounds of blood in one hour. And if the mass of blood in a human body be reckoned at an average at twenty-five pounds, it will follow, that *the whole mass of blood passes through the heart*, and consequently through the thousands of ramifications of the veins and arteries, *ten times every hour*, or about once every six minutes. We may acquire a rude idea of the force with which the blood is impelled from the heart, by considering the velocity with which water issues from a syringe, or from the pipe of a fire-engine. Could we behold these rapid motions incessantly going on within us, it would overpower our minds with astonishment, and even with terror. We should be apt to feel alarmed on making the smallest exertion, lest the parts of this delicate machine should be broken or deranged, and its functions interrupted. The arteries into which the blood is forced, branch in every direction through the body, like the roots and branches of a tree; running through the substance of the bones, and every part of the animal frame, until they are lost in such fine tubes as to be wholly invisible. In the parts where the arteries are lost to the sight, the veins take their rise; and, in the commencement, are also imperceptible.

RESPIRATION.—The organs of respiration are the *lungs.* They are divided into five lobes; three of which lie on the right, and two on the left side of the thorax. The substance of the lungs is chiefly composed of infinite ramifications of the trachea, or windpipe, which, after gradually becoming more and more minute, terminate in little cells or vesicles, which have a free communication with one another. At each inspiration, these pipes and cells are filled with air, which is again discharged by expiration. In this manner, a circulation of air, which is necessary to the existence of men and other animals, is constantly kept up as long as life remains. The air-cells of the lungs open into the windpipe, by which they communicate with the external atmosphere. The whole internal structure of the lungs is lined by a transparent membrane, estimated at only the thousandth part of an inch in thickness; but whose surface, from its various convolutions, measures fifteen square feet, which is equal to the external surface of the body. On this thin and extensive membrane innumerable veins and arteries are distributed, some of them finer than hairs; and through these vessels all the blood of the system is successively propelled, by a most curious and admirable mechanism. It has been computed that the lungs, on an average, contain about 280 cubic inches, or about five English quarts of air. At each inspiration, about forty cubic inches of air are received into the lungs, and the same quantity discharged at each expiration. On the supposition that twenty respirations take place in a minute, it will follow that, in one minute, we inhale 800 cubic inches; in an hour, 48,000; and in a day, one million one hundred and fifty-two thousand cubic inches—a quantity which would fill seventy-seven wine hogsheads, and would weigh fifty-three pounds Troy. By means of this function, a vast body of air is daily brought into contact with the mass of blood, and communicates to it its vivifying influence; and, therefore, it is of the utmost importance to health, that the air, of which we breathe so considerable a quantity, should be pure and uncontaminated with noxious effluvia.

In respiration, the air meets the blood in the lungs, and part of the oxygen of the atmosphere is absorbed by it, and imparts to it its red color. Part of the oxygen is also converted into carbonic acid by combining with carbon, or charcoal, in the lungs. In every instance, air which has been respired loses a part of its oxygen; the quantity varies at different times, according to the operation of certain external agents. It is reckoned that, upon an average, a man under ordinary circumstances consumes 45,000 cubic inches, or 15,500 grains of oxygen, in 24 hours. A quantity of carbonic acid is at the same time produced, which is generally somewhat less than the oxygen consumed, and may be reckoned at 40,000 cubic inches in 24 hours. It has been found that in the human species different individuals consume different quantities of oxygen, and of course return different quantities of carbonic acid. The breath expired has been shown to contain from 6 to 8 per cent. of carbonic acid It has been found that the nitrogen of the air inspired is sometimes returned in full volume, and sometimes is partially retained and disappears. On the whole, as respiration is one of the most important functions of animal life, on which our very existence depends, so we may plainly perceive, from the above and other circumstances, with what a variety of other functions it is connected, and on what a variety of minute and invisible processes its operations depend.

Digestion.—This process is performed by the *stomach*, which is a membranous and muscular bag, furnished with two orifices. By the one, it has a communication with a gullet, and by the other, with the bowels. The food, after being moistened by the saliva, is received into the stomach, where it is still further diluted by the *gastric juice*, which has the power of dissolving every kind of animal and vegetable substance. Part of it is afterward absorbed by the *lymphatic* and *lacteal* vessels, and carried into the circulating system, and converted into blood for supplying that nourishment which the perpetual waste of our bodies demands.

Perspiration is the evacuation of the juices of the body through the pores of the skin. It has been calculated that there are above *three hundred thousand millions of pores* in the glands of the skin which covers the body of a middle-sized man. Through these pores more than one-half of what we eat and drink passes off by *insensible* perspiration. If we consume eight pounds of food in a day, five pounds of it are insensibly discharged by perspiration. During a night of seven hours' sleep, we perspire about forty ounces, or two pounds and a half. At an average, we may estimate the discharge from the surface of the body, by sensible and insensible perspiration, at from half an ounce to four ounces an hour. This is a most wonderful part of the animal economy, and is absolutely necessary to our health, and even to our very existence. When *partially* obstructed, colds, rheumatisms, fevers, and other inflammatory disorders, are produced; and were it completely obstructed, the vital functions would be clogged and impeded in their movements, and death would inevitably ensue.

Sensation.—The *nerves* are generally considered as the instruments of sensation. They are soft white cords which proceed from the brain and spinal marrow. They come forth originally by pairs. Ten pair proceed from the medullary substance of the brain, which are distributed to all parts of the head and neck. Thirty pair proceed from the spinal marrow, through the vertebræ, to all the other parts of the body; being forty in all. These nerves, the ramifications of which are infinitely various and minute, are distributed upon the heart, lungs, blood-vessels, bowels, and muscles, until they terminate on the skin or external covering of the body. Impressions of external objects are received by the brain from the adjacent organs of sense, and the brain exercises its commands over the muscles and limbs by means of the nerves.

Without prosecuting these imperfect descriptions further, I shall conclude this very hasty sketch with the following summary of the parts of the body, in the words of Bonnet.—"The *bones*, by their joints and solidity, form the foundation of this fine machine: the *ligaments* are strings which unite the parts together: the *muscles* are fleshy substances, which act as elastic springs to put them in motion: the *nerves*, which are dispersed over the whole body, connect all the parts together: the *arteries* and *veins* like rivulets, convey life and health throughout: the *heart*, placed in the center, is the focus where the blood collects, or the acting power by means of which it circulates and is preserved: the *lungs*, by means of another power draw in the external air, and expel hurtful vapors: the *stomach* and intestines are the magazines where everything that is required for the daily supply is prepared: the *brain*, that seat of the soul, is formed in a manner suitable to the dignity of its inhabitant: the *senses*, which are the soul's ministers, warn it of all that is necessary either for its pleasure or use.* Adorable Creator! with what wonderful art hast thou formed us! Though the heavens did not exist to proclaim thy glory—though there were no created being upon earth but myself, my own body might suffice to convince me that thou art a God of unlimited power and infinite goodness."

This subject suggests a variety of moral and religious reflections, but the limits to which I am confined will permit me to state only the following:—

1. The economy of the human frame, when seriously contemplated, has a tendency to excite admiration and astonishment, and to *impress us with a sense of our continual dependence on a Superior Power.* What an immense multiplicity of machinery must be in action, to enable us to breathe, to feel, and to walk! Hundreds of bones of diversified forms, connected together by various modes of articulation; hundreds of muscles to produce motion, each of them acting in at least ten different capacities (see p. 36); hundreds of tendons and ligaments to connect the bones and muscles; hundreds of arteries to convey the blood to the remotest part of the system; hundreds of veins to bring it back to its reservoir the heart; thousands of glands secreting humors of various kinds from the blood; thousands of lacteal and lymphatic tubes, absorbing and conveying nutriment to the circulating fluid; millions of pores, through which the perspiration is continually issuing; an infinity of ramifications of nerves, diffusing sensation throughout all the parts of this exquisite machine; and the heart at every pulsation exerting a force of a hundred thousand pounds, in order to preserve all this complicated machinery in constant operation! The whole of this vast system of mechanism must be in action before we can walk across our apartments! We admire the operation of a steam-engine, and the force it exerts. But, though it is constructed of the hardest materials which the mines can supply, in a few months, some of its essential parts are worn and deranged, even although its action should be frequently discontinued. But the animal machine, though constructed, for the most part, of the softest and most flabby substances, can go on without intermission in all its diversified movements, by night and by day, for the space of eighty or a hundred years! the heart giving ninety-six thousand strokes every twenty-four hours, and the whole mass of blood rushing through a thousand pipes of all sizes every four minutes! And is it *man* that governs these nice and complicated movements? Did *he* set the heart in motion, or indue it with the muscular force it exerts? And when it has ceased to beat, can *he* command it again to resume its functions? Man knows neither the secret springs of the machinery within him, nor the half of the purposes for which they serve, or of the movements they perform. Can anything more strikingly

---

* Contemplation of Nature, vol i, p. 64

demonstrate our dependence every moment on a Superior Agent, and that it is "in God we live and move and have our being?" Were a single pin of the machinery within us, and over which we have no control, either broken or deranged, a thousand movements might instantly be interrupted, and our bodies left to crumble into the dust.

It was considerations of this kind that led the celebrated physician Galen, who was a skeptic in his youth, publicly to acknowledge that a Supreme Intelligence must have operated in ordaining the laws by which living beings are constructed. And he wrote his excellent treatise, "On the uses of the parts of the human frame," as a solemn hymn to the Creator of the world. "I first endeavor from His works," he says, "to know myself, and afterward by the same means to show him to others; to inform them how great is his wisdom, his goodness, his power." The late Dr. Hunter has observed, that Astronomy and Anatomy are the studies which present us with the most striking view of the two most wonderful attributes of the Supreme Being. The first of these fills the mind with the idea of his immensity, in the largeness, distances, and number of the heavenly bodies; the last astonishes us with his intelligence and art, in the variety and delicacy of animal mechanism.

2. The study of the animal economy has a powerful tendency *to excite emotions of gratitude.* Man is naturally a thoughtless and *ungrateful* creature. These dispositions are partly owing to *ignorance* of the wonders of the human frame, and of the admirable economy of the visible world; and this ignorance is owing to the want of those specific instructions which ought to be communicated by parents and teachers, in connection with religion. For there is no rational being, who is acquainted with the structure of his animal system, and reflects upon it with the least degree of attention, but must feel a sentiment of admiration and gratitude. The science which unfolds to us the economy of our bodies, shows us, on what an infinity of springs and motions and adaptations, our life and comfort depend. And when we consider, that all these movements are performed without the least care or laborious effort on our part, if we be not altogether brutish, and insensible of our dependence on a Superior Power, we must be filled with emotions of gratitude toward Him "whose hands have made and fashioned us, and who giveth us life, and breath, and all things." Some of the motions to which I have adverted depend upon our will; and with what celerity do they obey its commands? Before we can rise from our chair, and walk across our apartment, a hundred muscles must be set in motion; every one of these must be relaxed or constricted, just to a certain degree, and no more; and all must act harmoniously at the same instant of time; and at the command of the soul, all these movements are instantaneously performed. When I wish to lift my hand to my head, every part of the body requisite to produce the effect is put in motion: the nerves are braced, the muscles are stretched or relaxed, the bones play in their sockets, and the whole animal machine concurs in the action, as if every nerve and muscle had heard a sovereign and resistless call. When I wish, the next moment, to extend my hand to my foot, all these muscles are thrown into a different state, and a new set are brought along with them into action; and thus we may vary, every moment, the movements of the muscular system, and the mechanical actions it produces, by a simple change in our volition. Were we not daily accustomed to such varied and voluntary movements, or could we contemplate them in any other machine, we should be lost in wonder and astonishment.

Beside these voluntary motions, there are a thousand important functions which have no dependence upon our will. Whether we think of it or not, whether we be sleeping or waking, sitting or walking—the heart is incessantly exerting its muscular power at the center of the system, and sending off streams of blood through hundreds of pipes; the lungs are continually expanding and contracting their thousands of vesicles, and imbibing the vital principle of the air; the stomach is grinding the food; the lacteals and lymphatics are extracting nourishment for the blood; the liver and kidneys drawing off their secretions; and the perspiration issuing from millions of pores. These, and many other important functions with which we are unacquainted, and over which we have no control, ought to be regarded as the immediate agency of the Deity within us, and should excite our incessant admiration and praise.

There is one peculiarity in the constitution of our animal system, which we are apt to overlook, and for which we are never sufficiently grateful; and that is, *the power it possesses of self-restoration.* A wound heals up of itself; a broken bone is made firm again by a callus; and a dead part is separated and thrown off. If all the wounds we have ever received were still open and bleeding afresh, to what a miserable condition should we be reduced? But by a system of internal powers, beyond all human comprehension as to the mode of their operation, such dismal effects are effectually prevented. In short, when we consider, that health depends upon such a numerous assemblage of moving organs, and that a single spring out of action might derange the whole machine, and put a stop to all its complicated movements, can we refrain from joining with the Psalmist in his pious exclamation, and grateful resolution, "How precious are thy wonderful contrivances concerning me, O God! how great is the sum of them! I will praise thee; for I am fearfully and wonderfully made. Marvelous are thy works, and that my soul knoweth right well."

Omitting the consideration of several other departments of science, I shall, in the meantime, notice only another subject connected with religion, and that is

HISTORY.

History embraces a record and description of past facts and events in reference to all the nations and ages of the world, in so far as they are known, and have been transmitted to our time.—As Natural History contains a record of the operations of the Creator in the material world, so Sacred and Civil History embraces a record of his transactions in the moral and intellectual world, or, in other words, a detail of the plans and operations of his Providence, in relation to the inhabitants of our globe.

During the period of 3500 years from the creation of man, the Sacred History contained in the Old Testament is our only source of information in reference to the state of mankind, and the events which happened to the human race throughout that long interval. From the creation of Adam to the Deluge—a period of about 2000 years, according to the Septuagint chronology—we have no authenticated account of what happened to the inhabitants of the world, but that which is recorded in the first eight chapters of the book of Genesis. And during a period of 1500 years after the flood, the Sacred History is still our only sure guide as to the events which took place among the nations of the earth. This history, however, relates chiefly to the inhabitants of Judea, and the surrounding nations,—so that the greater portion of the history of man, in reference to all the other nations of the world, remains to be learned in a future state. The Old Testament records carry down our views of the history of man to the period of the Jewish captivity, and to about a hundred years posterior to that event, that is, to within four or five hundred years of the Christian era. About this period *Civil History* becomes definite and authentic, and fills up, in some measure, the chasm which is left in the Sacred History, so that, from this period downward to the present time — with the exception of the New Testament records—we are indebted to civil or profane history, written by men of different nations, for all our knowledge of the transactions of mankind and of the events which have befallen them during the bypast period of 2500 years.

Civil history has been divided into *Ancient* and *Modern* History. Ancient history stretches back as far as the authentic records of nations can carry us; but we have no records to be depended upon, separate from Revelation, which can carry us farther back in the lapse of past ages, than about a thousand years before the Christian era. This department of historic record comprehends the history of the *Egyptians*—the *Assyrians* and *Babylonians* — the *Jews* and *Phenicians* — the *Medes* and *Persians*—the *Scythians* and *Celts*—the *Carthagenians*,— and particularly the history of the *Greeks* and of the *Romans*, which forms by far the larger portion of ancient history, extending from the building of Rome in the year 753 before Christ, to the subversion of the Roman empire in the 6th century of the Christian era, a period of about 1300 years.— *Modern* history commences where ancient history ends, about the 6th or 7th century, and comprises the history of France, Germany, Britain, Spain, Portugal, Italy, and other countries in Europe, together with what is known in modern times respecting the events which have happened in the kingdoms of Asia and Africa, and in the settlements of Australasia and America. In reference to all such historical records, it is deeply to be lamented that they contain little else than details of wars, slaughters and devastations, and chiefly present to our view pictures of extortion, assassinations, wholesale robberies, the destruction of empires, the burning of cities, and the desolation of provinces. From these records, however, we may learn such instructions as the following:—

Through the medium of sacred history we learn the period and the manner of man's creation;— the reason of his fall from the primitive state of integrity in which he was created, and the dismal consequences which ensued;—the various movements of providence in order to his recovery, and the means by which human redemption was achieved;—the manner in which the Gospel was at first promulgated, the countries into which it was carried, and the important effects it produced.— Through the medium of civil history we learn the deep and universal depravity of mankind, as exhibited in the wars, dissensions, and ravages which have desolated our fallen race in every period and in every land; we learn the desperate wickedness of the human heart in the more private acts of ferocity, cruelty, and injustice, which in all ages men have perpetrated upon each other;—we behold the righteousness of the supreme Ruler of the world, and the equity of his administration in the judgments which have been inflicted on wicked nations; and the improbability, nay, the *impossibility* of men being ever restored to moral order and happiness, without a more extensive diffusion of the blessings of the gospel of peace, and a more cordial acquiescence in the requirements of the divine law.

Such being some of the benefits to be derived from history, it requires no additional arguments to show that this branch of knowledge should occasionally form a subject of study to every intelligent Christian. But in order to render the study of history subservient to the interests of religion, it is not enough merely to gratify our curiosity and imagination, by following out a succession of memorable events, by tracing the progress of armies and of battles, and listening to the groans of the vanquished and the shouts of conquerors. This would be to study history merely as skeptics, as atheists, or as writers of novels.— When we contemplate the facts which the historian presents to our view, we ought to raise our eyes to Him who is the Governor among the nations, "who doth according to his will in the armies of heaven and among the inhabitants of the earth," and who overrules the jarring interests of mortals, for promoting the prosperity of that kingdom which shall never be moved. We should view the immoral propensities and dispositions of mankind as portrayed in the page of history, as evidences of the depravity of our species, and as excitements to propagate, with unremitting energy, the knowledge of that Religion, whose sublime doctrines and pure precepts alone can counteract the stream of human corruption, and unite all nations in one harmonious society. We should view the contests of nations, and the results with which they are accompanied, as guided by that invisible hand which "mustereth the armies to the battle;" and should contemplate them either as the accomplishment of Divine predictions, as the inflictions of retributive justice, as paving the way for the introduction of rational liberty and social happiness among men, or as ushering in that glorious period, when "the knowledge of the Lord shall cover the earth," and the nations shall learn war no more.

Thus I have taken a very cursory survey of some of those sciences which stand in a near relation to the objects of Religion; and which may indeed be considered as forming so many of its subordinate branches. There are many other departments of knowledge, which at first view do not seem to have any relation to Theological science; and yet, on a closer inspection, will be found to be essentially connected with the several subjects of which I have been treating. For example—some may be apt to imagine that Arithmetic, Geometry, Trigonometry, and other branches of Mathematics, can have no relation to the leading objects of Religion. But if these sciences had never been cultivated, the most important discoveries of astronomy, geography, natural philosophy, and chemistry, would never have been made; ships could not have been navigated across the ocean; distant continents, and the numerous "isles of the sea," would have remained unexplored, and their inhabitants left to grope in the darkness of heathenism; and most of those instruments and engines by which the condition of the human race will be gradually meliorated, and the influence of Christianity extended, would never have been invented. Such is the dependence of every branch of useful knowledge upon another, that were any one portion of science, which has a practical tendency, to be discarded, it would prevent to a certain degree the improvement of every other. And consequently, if any one science can be shown to have a connection with religion, all the rest must likewise stand in a certain relation to it. It must, therefore, have a pernicious effect on the minds of the mass of the Christian world, when preachers in their sermons endeavor to undervalue scientific knowledge, by attempting to contrast it with the doctrines of Revelation. It would be just as reasonable to attempt to contrast the several doctrines, duties, and facts recorded in the New Testament, with each other, in order to determine their relative importance, and to show which of them might be altogether overlooked and discarded.—The series of facts and of divine revelations comprised in the Bible; the moral and political events which diversify the history of nations; and the physical operations that are going on among the rolling worlds on high, and in the chemical changes of the invisible atoms of matter—are all parts of *one* comprehensive system, under the direction of the Eternal Mind; every portion of which must have a certain relation to the whole. And therefore, instead of attempting to degrade one part of the Divine fabric, in order to enhance another, our duty is to take an expansive view of the whole, and to consider the symmetry and proportion of its parts, and their mutual bearings and relations, in so far as our opportunities and the limited faculties of our minds will permit.

If the remarks which have been thrown out in this chapter, respecting the connection of the Sciences with Religion, have any foundation, it will follow—that Sermons, Lectures, systems of Divinity, and Religious Periodical works, should embrace occasional illustrations of such subjects, for the purpose of expanding the conceptions of professed Christians, and of enabling them to take large and comprehensive views of the perfections and the providence of the Almighty.—It is much to be regretted, that so many members of the Christian church are absolute strangers to such studies and contemplations; while the time and attention that might have been devoted to such exercises, have in many cases been usurped by the most groveling affections, by foolish pursuits, by gossiping chitchat, and slanderous conversation. Shall the most trifling and absurd opinions of ancient and modern heretics be judged worthy of attention, and occupy a place in Religious journals, and even in discussions from the pulpit; and shall "the mighty acts of the Lord," and the visible wonders of his power and wisdom, be thrown completely into the shade! To survey with an eye of intelligence the wide-extended theater of the Divine operations—to mark the agency of the Eternal Mind in every object we behold, and in every movement within us and around us, are some of the noblest attainments of the rational soul; and, in conjunction with every other Christian study and acquirement, are calculated to make "the man of God perfect, and thoroughly furnished unto every good work." By such studies we are, in some measure, assimilated to the angelic tribes, whose powers of intellect are forever employed in such investigations; and are gradually prepared for bearing a part in their immortal hymn—"Great and marvelous are thy works, Lord God Almighty; just and true are thy ways, thou King of Saints! Thou art worthy to receive glory and honor and power; for thou hast created all things, and for thy pleasure they are and were created."

CHAPTER III.

THE RELATION WHICH THE INVENTIONS OF HUMAN ART BEAR TO THE OBJECTS OF RELIGION.

In this chapter I shall briefly notice a few philosophical and mechanical inventions, which have an obvious bearing on Religion, and on the general propagation of Christianity among the nations.

The first, and perhaps the most important of the inventions to which I allude, is the **Art of Printing.** This art appears to have been invented (at least in Europe) about the year 1430, by one Laurentius, or Laurence Koster, a native of Haerlem, a town in Holland. As he was walking in a wood near the city, he began to cut some letters upon the rind of a beech tree, which, for the sake of gratifying his fancy, being impressed on paper, he printed one or two lines as a specimen for his grand-children to follow. This having succeeded, he meditated greater things: and, first of all, invented a more glutinous writing-ink, because he found the common ink sunk and spread; and thus formed whole pages of wood with letters cut upon them.* By the gradual improvement of this art, and its application to the diffusion of knowledge, a new era was formed in the annals of the human race, and in the progress of science, religion, and morals. To it we are chiefly indebted for our deliverance from ignorance and error, and for the most of those scientific discoveries and improvements in the arts which distinguish the period in which we live. Without its aid, the Reformation from Popery could scarcely have been achieved; for had the books of Luther, one of the first reformers, been multiplied by the slow process of hand-writing and copying, they could never have been diffused to any extent; and the influence of bribery and of power might have been sufficient to have arrested their progress, or even to have erased their existence. But, being poured forth from the press in thousands at a time, they spread over the nations of Europe, like an inundation, and with a rapidity which neither the authority of princes, nor the schemes of priests and cardinals, nor the bulls of popes, could counteract or suspend. To this noble invention it is owing that copies of the Bible have been multiplied to the extent of many millions—that ten thousands of them are to be found in every Protestant country—and that the poorest individual who expresses a desire for it, may be furnished with the "Word of Life," which will guide him to a blessed immortality. That Divine light which is destined to illuminate every region of the globe, and to sanctify and reform men of all nations, and kindreds, and tongues, is accelerated in its movements, and directed in its course through the nations, by the invention of the Art of Printing; and ere long it will distribute among the inhabitants of every land, the "Law and the Testimony of the Most High," to guide their steps to the regions of eternal bliss. In short, there is not a more powerful engine in the hand of Providence, for diffusing the knowledge of the nature and the will of the Deity, and for accomplishing the grand objects of Revelation, than the art of multiplying books, and of conveying intelligence through the medium of the press. Were no such art in existence, we cannot conceive how an extensive and universal propagation of the doctrines of Revelation could be effected, unless after the lapse of an indefinite number of ages. But with the assistance of this invention, in its present improved state, the island of Great Britain alone, within less than one hundred years, could furnish a copy of the Scriptures to every inhabitant of the world, and could defray the expense of such an undertaking, with much more ease, and with a smaller sum, than were necessary to finish the political warfare in which we were lately engaged.

---

* I am aware that the honor of this invention has been claimed by other cities beside Haerlem, particularly by Strasburg, and Mentz, a city of Germany; and by other individuals beside Laurentius, chiefly by one *Faust*, commonly called Dr. Faustus; by Schoeffer, and by Guttenberg. It appears that the art, with many of its implements, was stolen from Laurentius by one of his servants, whom he had bound by an oath to secrecy, who fled to Mentz, and first commenced the process of printing in that city. Here the art was improved by Faust and Schoeffer, by their invention of *metallic*, instead of *wooden* types, which were first used. When Faust was in Paris, disposing of some Bibles he had printed, at the low price (as was then thought) of sixty crowns, the number, and uniformity of the copies he possessed, created universal agitation and astonishment. Informations were given to the police against him as a magician, his lodgings were searched, and a great number of copies being found, they were seized; the red ink with which they were embellished was said to be his blood: it was seriously adjudged that he was in league with the Devil; and if he had not fled from the city, most probably he would have shared the fate of those whom ignorant and superstitious judges, at that time, condemned for witchcraft. From this circumstance, let us learn to beware how we view the inventions of genius, and how we treat those whose ingenious contrivances may afterward be the means

These considerations teach us that the ingenious inventions of the human mind are under the direction and control of the Governor of the world—are intimately connected with the accomplishment of the plans of his providence; and have a tendency, either directly or indirectly, to promote, over every region of the earth, the progress and extension of the kingdom of the Redeemer. They also show us from what small beginnings the most magnificent operations of the Divine economy may derive their origin. Who could have imagined that the simple circumstance of a person amusing himself by cutting a few letters on the bark of a tree, and impressing them on paper, was intimately connected with the mental illumination of mankind? and that the art which sprung from this casual process was destined to be the principal mean of illuminating the nations, and of conveying to the ends of the earth the "salvation of our God?" But "He who rules in the armies of heaven, and among the inhabitants of the earth," and who sees "the end from the beginning," overrules the most minute movements of all his creatures, in subserviency to his ultimate designs, and shows himself in this respect to be "wonderful in counsel and excellent in working."

The MARINER'S COMPASS.—Another invention which has an intimate relation to religion, is the *Art of Navigation and the invention of the* MARINER'S COMPASS. Navigation is the art of conducting a ship through the sea from one port to another. This art was partly known and practiced in the early ages of antiquity by the Phenicians, the Carthaginians, the Egyptians, the Romans, and other nations of Europe and Asia. But they had no guide to direct them in their voyages, except the sun in the day-time, and the stars by night. When the sky was overcast with clouds, they were thrown into alarms, and durst not venture to any great distance from the coast, lest they should be carried forward in a course opposite to that which they intended, or be driven against hidden rocks, or unknown shores. The danger and difficulty of the navigation of the ancients on this account may be learned from the deliberations, the great preparations, and the alarms of Homer's heroes, when they were about to cross the Ægean sea, an extent of not more

---

of enlightening and meliorating mankind.—See Appendix, Note IX.

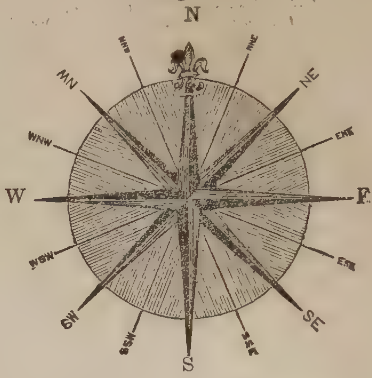
Various improvements have been made of late years in the art of Printing. The art of *Stereotyping*, which was invented by Mr. Ged, of Edinburgh, in 1725, but was not brought into general use until after the beginning of the present century—is now extensively used, both in Great Britain and America, in the printing of such books as have an extensive circulation. When a page is intended to be *stereotyped*, the types are, in the first instance, put up in the usual way; but instead of being carried to the press, the page is plastered over with liquid stucco to the thickness of about half an inch, so that a level cake is formed on the surface of the types. As soon as the stucco hardens, the cake is separated from the types, and on being turned up, shows a complete mold-like representation of the faces of the types; and there being no longer any use for the types, they are carried off and distributed. After the cake is hardened, by putting it into an oven, it is next laid in a square iron pan, at the bottom of which is a movable plate, upon which the mold is placed, with its face downward. The pan is then immersed in a pot of molten lead, and when the lead has run into the mold side of the cake, and formed a thin plate all over, there is produced the perfect appearance of the faces of the types on which the stucco was plastered. The stereotype plates, thus prepared, are next taken to the printing-office and made ready for the press, by placing them on iron or wooden blocks, so that both plate and block make up the exact hight of a page of real types.—In this manner any number of copies of a book may be printed at any time, without again incurring the trouble and expense of re-setting the types, as is necessary to be done in printing new editions. Chambers' "Edinburgh Journal" is regularly stereotyped in this way. The types being put up on the premises of the publishers, are sent off in pages to a stereotype foundery, where two sets of plates are molded. One set of plates is kept for use in Edinburgh, and the other sent in a box, by the Royal Mail or Steam vessel, to London, where it is immediately subjected to a steam press, and in a few hours made to produce 20,000 or more printed sheets.

Steam-printing—which is now coming in general use—appears to have been first introduced by Mr. Konig, a German, about 1804. The "Times" newspaper, of November 28, 1814, appears to have been the first ever printed by machinery propelled by steam, and the numbers of that paper have been thrown off by the same process ever since. A machine of this description, with one cylinder, throws off from 900 to 1200 sheets in an hour on one side, requiring two boys, one to lay on the paper, and another to receive it when printed A machine with two cylinders throws off at the rate of from 1600 to 2200 an hour, requiring two boys to lay on the sheets, and two to take them off—exclusively for newspapers. A machine similar to that used by the "Times," with 4 printing cylinders, requiring the attendance of 8 boys, throws off about 4000 sheets an hour. By the erection of such steam presses, the three grand requisites, speediness of execution, quantity, and cheapness of labor, are secured to an extent which could scarcely have been anticipated in a preceding age, and which is calculated to supply the exigencies of the times in which we live, when knowledge of every description is rapidly diffusing itself among all ranks of the community.

than 150 miles; and the expedition of the Argonauts under Jason, across the sea of Marmora and the Euxine, to the island of Colchis, a distance of only four or five hundred miles, was viewed as a most wonderful exploit, at which even the gods themselves were said to be amazed. The same thing appears from the narration we have in the Acts of the Apostles, of Paul's voyage from Cesarea to Rome. "When," says Luke, "neither sun nor stars in many days appeared, and no small tempest lay on us, all hope that we should be saved was then taken away." Being deprived of these guides, they were tossed about in the Mediterranean, not knowing whether they were carried to north, south, east, or west. So that the voyages of antiquity consisted chiefly in creeping along the coast, and seldom venturing beyond sight of land: they could not, therefore, extend their excursions by sea to distant continents and nations; and hence the greater portion of the terraqueous globe and its inhabitants were to them altogether unknown. It was not before the invention of the mariner's compass that distant voyages could be undertaken, that extensive oceans could be traversed, and an intercourse carried on between remote continents and the islands of the ocean.

It is somewhat uncertain at what precise period this noble discovery was made; but it appears pretty evident that the mariner's compass was not commonly used in navigation before the year 1420, or only a few years before the invention of printing.* The loadstone, in all ages, was known to have the property of attracting iron; but its tendency to point toward the north and south seems to have been unnoticed until the beginning of the twelfth century. About that time, some curious persons seem to have amused themselves by making to swim, in a basin of water, a loadstone suspended on a piece of cork; and to have remarked, that, when left at liberty, one of its extremities pointed to the north. They had also remarked, that, when a piece of iron is rubbed against the loadstone, it acquires also the property of turning toward the north, and of attracting needles and filings of iron. From one experiment to another, they proceeded to lay a needle, touched with the magnet, on two small bits of straw floating on the water, and to observe that the needle invariably turned its point toward the north. The first use they seem to have made of these experiments, was to impose upon simple people by the appearance of *magic*. For example, a hollow swan, or the figure of a mermaid, was made to swim in a basin of water, and to follow a knife with a bit of bread upon its point, which had been previously rubbed on the loadstone. The experimenter convinced them of his power, by commanding, in this way, a needle laid on the surface of the water, to turn its point from the north to the east, or in any other direction. But some geniuses, of more sublime and reflective powers of mind, seizing upon these hints, at last applied these experiments to the wants of navigation, and constructed an instrument, by the help of which the mariner can now direct his course to distant lands, through the vast and pathless ocean. The following figure gives a general representation of the mariner's compass.

Fig. 27.



In consequence of the discovery of this instrument, the coasts of almost every land on the surface of the globe have been explored, and a regular intercourse opened up between the remotest regions of the earth. Without the help of this noble invention, America, in all probability, would never have been discovered by the eastern nations, the vast continent of New Holland, the numerous and interesting islands in the Indian and Pacific oceans, the isles of Japan, and other immense territories inhabited by human beings, would have remained as much unknown and unexplored as if they had never existed. And as the nations of Europe and the western parts of Asia were the sole depositories of the records of Revelation, they could never have conveyed the blessings of salvation to remote countries, and to unknown tribes of mankind, of whose existence they were entirely ignorant. Even although the whole terraqueous globe had been sketched out before them, in all its aspects and bearings, and ramifications of islands, continents, seas, and oceans, and the moral and political state of every tribe of its inhabitants displayed to view, without a guide to direct their course through the billows of the ocean, they could have afforded no light and no relief to cheer the distant nations "who sit in darkness and in the shadow of death." Though the art of printing had been invented; though millions of Bibles were now prepared, adequate to the supply of all the "kindreds of the heathen;" though ships in abundance were equipped for the enterprise, and thousands of missionaries ready to embark, and to devote their lives to the instruction of the Pagan world; all would be of no avail, and the "salvation of God" could never be proclaimed to the ends of the world, unless they had the mariner's compass to guide their course through the trackless ocean.

In this invention, then, we behold a proof of the agency of Divine Providence in directing the efforts of human genius to subserve the most important designs, and contemplate a striking specimen of the "manifold wisdom of God." When the pious and contemplative Israelite reflected on the declaration of the prophets, that "the glory of Jehovah should be revealed, and that all flesh should see it together,"—from the state of the arts which then existed, he must have felt many difficulties in forming a conception of the *manner* in which such predictions should be realized. "The great and wide sea," now termed the Mediterranean, formed the boundary of his view, beyond which he was unable to penetrate. Of the continents and "the isles afar off," and of the far more spacious oceans that lay between, he had no knowledge; and how "the ends of the earth" were to be reached, he could form no conception; and, in the midst of his perplexing thoughts, he could find satisfaction only in the firm belief that "with God all things are possible." But now we are enabled not only to contemplate the grand designs of the Divine economy, but the principal means by which they shall all, in due time, be accomplished, in consequence of the progress of science and art, and of their consecration to the rearing and extension of the Christian church.

---

* The invention of the compass is usually ascribed to Flavio Gioia, of Amalfi, in Campania, about the year 1302; and the Italians are strenuous in support of this claim. Others affirm that Marcus Paulus, a Venetian, having made a journey to China, brought back the invention with him in 1260. The French also lay claim to the honor of this invention, from the circumstance that all nations distinguish the North point of the card by a *fleur de lis;* and, with equal reason, the English have laid claim to the same honor, from the name *compass*, by which most nations have agreed to distinguish it. But whoever were the inventors, or at whatever period this instrument was first constructed, it does not appear that it was brought into general use before the period mentioned in the text.

The two inventions to which I have now adverted, may, perhaps, be considered as among the most striking instances of the connection of human art with the objects of Religion. But there are many other inventions which, at first view, do not appear to bear so near a relation to the progress of Christianity, and yet have an ultimate reference to some of its grand and interesting objects.

The TELESCOPE.—We might be apt to think, on a slight view of the matter, that there can be no immediate relation between the grinding and polishing of an optic glass, and fitting two or more of them in a tube—and the enlargement of our views of the operations of the Eternal Mind. Yet the connection between these two objects, and the dependence of the latter upon the former, can be fairly demonstrated.—The son of a spectacle-maker of Middleburg in Holland, happening to amuse himself in his father's shop, by holding two glasses between his finger and his thumb, and varying their distances, perceived the weathercock of the church spire opposite to him, much larger than ordinary, and apparently much nearer, and turned upside down. This new wonder excited the amazement of the father; he adjusted two glasses on a board, rendering them movable at pleasure; and thus formed the first rude imitation of a perspective glass, by which distant objects are brought near to view. Galileo, a philosopher of Tuscany, hearing of the invention, set his mind to work, in order to bring it to perfection. He fixed his glasses at the end of long organ-pipes, and constructed a telescope, which he soon directed to different parts of the surrounding heavens. He discovered four moons revolving round the planet Jupiter—spots on the surface of the Sun, and the rotation of that globe around its axis—mountains and valleys in the Moon—and numbers of fixed stars where scarcely one was visible to the naked eye. These discoveries were made about the year 1610, a short time after the first invention of the telescope. Since that period, this instrument has passed through various degrees of improvement, and, by means of it, celestial wonders have been explored in the distant spaces of the universe, which, in former times, were altogether concealed from mortal view. By the help of telescopes, combined with the art of measuring the distances and magnitudes of the heavenly bodies, our views of the Grandeur of the Almighty, of the plenitude of his Power, and of the *extent* of his universal Empire, are extended far beyond what could have been conceived in former ages. Our prospects of the range of the divine operations are no longer confined within the limits of the world we inhabit; we can now plainly perceive, that the kingdom of God is not only "an everlasting dominion," but that it extends through the unlimited regions of space, comprehending within its vast circumference thousands of suns, and ten thousands of worlds, all arranged in majestic order, at immense distances from one another, and all supported and governed "by Him who rides on the Heaven of heavens," whose greatness is unsearchable, and whose understanding is infinite.

The telescope has also demonstrated to us the *literal truth* of those scriptural declarations which assert that the stars are "innumerable." Before the invention of this instrument, not more than about a thousand stars could be perceived by the unassisted eye in the clearest night. But this invention has unfolded to view not only thousands, but hundreds of thousands, and millions, of those bright luminaries, which lie dispersed in every direction throughout the boundless dimensions of space. In the *Milky Way*—a whitish zone or circle which surrounds the heavens—more than ten millions of stars might be distinguished by means of the best telescopes. And the higher the magnifying and illuminating powers of the telescope are, the more numerous those celestial orbs appear; leaving us no room to doubt, that countless myriads more lie hid in the distant regions of creation, far beyond the reach of the finest glasses that can be constructed by human skill, and which are known only to Him "who counts the number of the stars, and calls them by their names."

In short, the telescope may be considered as serving the purpose of a vehicle for conveying us to the distant regions of space. We would consider it as a wonderful achievement, could we transport ourselves two hundred thousand miles from the earth, in the direction of the Moon, in order to take a nearer view of that celestial orb. But this instrument enables us to take a much nearer inspection of that planet than if we had actually surmounted the force of gravitation, traversed the voids of space, and left the earth 230,000 miles behind us. For, supposing such a journey to be accomplished, we should still be ten thousand miles distant from that orb. But a telescope which magnifies objects 240 times, can carry our views within ONE thousand miles of the Moon; and a telescope, such as Sir W. Herschel's 40 feet reflector, which magnifies 6000 times, would enable us to view the mountains and valleys of the Moon, as if we were transported to a point about 40 miles from her surface.* We can

---

* Though the highest magnifying power of Sir W. Herschel's large telescope, which is now dismantled, was estimated at six thousand times, yet, it does not appear that he ever applied this power with success, when viewing the moon and the planets. The deficiency of light, when using so high a power, would render the view of these objects less satisfactory than when viewed with a power of only a thousand times. Still, it is quite certain, that if any portions of the moon's surface were viewed through an instrument of such a power they would appear as *large* (but *not nearly so bright and distinct*) as if we were placed about 40 miles distant from that body. The enlargement of the angle of vision, in this case, or the apparent distance at which the moon would be contemplated, is found by dividing the moon's distance—240,000 miles, by 6000, the magnifying power of the telescope, which produces a quotient of 40—the number of miles at which the moon would appear to be placed from the eye of the observer. Sir W. Herschel appears to have used the highest powers of his telescopes only, or chiefly, when viewing some very minute objects in the region of the stars. The powers he generally used, and with which he made most of his discoveries, were, 227, 460, 754, 932, and occasionally 2010, 3168, and 6450, for the purpose of making experiments of their effect on double stars, etc.

Lord Oxmantown, now Earl of Rosse, after a labor of about three years, completed in 1845 the construction of his reflecting telescope, which is of much larger dimensions than the 40 feet telescope of Herschel. The casting of this speculum took place in April, 1842. The metal is 6 feet view the magnificent system of the planet Saturn, by means of this instrument, as distinctly, as if we had performed a journey eight hundred millions of miles in the direction of that globe; which, at the rate of 50 miles an hour, would require a period of more than eighteen hundred years to accomplish. By the telescope, we can contemplate the region of the fixed stars, their arrangement into systems, and their immense numbers, with the same distinctness and amplitude of view, as if we had actually taken a flight of ten hundred thousand millions of miles into those unexplored and unexplorable regions, which could not be accomplished in several millions of years, though our motion were as rapid as a ball projected from a loaded cannon. We would justly consider it as a noble endowment for enabling us to take an extensive survey of the works of God, if we had the faculty of transporting ourselves to such immense distances from the sphere we now occupy; but by means of the telescopic tube, we may take nearly the same ample views of the dominions of the Creator, without stirring a foot from the limits of our terrestrial abode. This instrument may, therefore, be considered as a providential gift bestowed upon mankind, to serve, in the meantime, as a *temporary substitute*, for those powers of rapid flight with which the seraphim are endowed, and for those superior faculties of motion with which man himself may be invested, when he arrives at the summit of moral perfection.[*]

The MICROSCOPE.—The *Microscope* is another instrument, constructed on similar principles, which has greatly expanded our views of the "manifold wisdom of God." This instrument, which discovers to us small objects invisible to the naked eye, was invented soon after the invention and improvement of the telescope. By means of this optical contrivance, we perceive a variety of wonders in almost every object in the animal, the vegetable, and the mineral kingdoms. We perceive that every particle of matter, however minute, has a determinate form—that the very scales on the skin of a haddock are all beautifully interwoven and variegated, like pieces of network, which no art can imitate—that the points of the prickles of vegetables, though magnified a thousand times, appear as sharp and well polished as to the naked eye—that every particle of the dust on a moth or a butterfly's wing, is a beautiful and regularly organized feather—that every hair of our head is a hollow tube, with bulbs and roots, furnished with a variety of threads and filaments—and that the pores in our skin, through which the sweat and perspiration flow, are so numerous and minute, that a grain of sand would cover a hundred and twenty-five thousand of them. We perceive animated beings in certain liquids, so small that fifty thousand of them would not equal the size of a mite; and yet each of these creatures is furnished with a mouth, eyes, stomach, blood-vessels, and other organs for the performance of animal functions. In a stagnant pool, which is covered with a greenish scum during the summer months, every drop of the water is found to be a world teeming with thousands of inhabitants. The moldy substance which usually adheres to damp bodies, exhibits a forest of trees and plants, where the branches, leaves, and fruit, can be plainly distinguished. In a word, by this admirable instrument we behold the same Almighty hand which rounded the spacious globe on which we live, and the huge masses of the planetary orbs, and directs them in their rapid motions through the sky,—employed, at the same moment, in rounding and polishing ten thousand minute transparent globes in the eye of a fly; and boring and arranging veins and arteries, and forming and clasping joints and claws, for the movements of a mite! We thus learn the admirable and astonishing effects of the Wisdom of God, and that the Divine Care and Benevolence are as much displayed in the construction of the smallest insect, as in the elephant or the whale, or in those ponderous globes which roll around us in the sky. These, and thousands of other views which the microscope exhibits, would never have been displayed to the human mind, had they not been opened up by this admirable invention.

In fine, by means of the two instruments to which I have now adverted, we behold Jehovah's empire extending to infinity on either hand. By the telescope we are presented with the most astonishing displays of his *omnipotence*, in the immense number, the rapid motions, and the inconceivable magnitude, of the celestial globes;—and by the microscope, we behold, what is still more inconceivable, a display of his unsearchable wisdom in the Divine mechanism, by which a drop of water is peopled with myriads of inhabitants—a fact, which, were it not subject to ocular demonstration, would far exceed the limits of human conception or belief. We have thus the most striking and sensible evidence, that, from the immeasurable luminaries of heaven, and from the loftiest seraph that stands before the throne of God, down to this lower world, and to the smallest microscopic animalcule that eludes the finest glass—HE is everywhere present, and, by his power, intelligence, and agency, animates, supports, and directs the whole. Such views and contemplations naturally lead us to advert to the character of God, as delineated by the sacred writers, that "He is of great power and mighty in strength;" that "His understanding is infinite;" that "His works are wonderful;" that "His operations are unsearchable, and past finding out;" and they must excite the devout mind to join with fervor in the language of adoration and praise—

When thy amazing works, O God!
My mental eye surveys,
"Transported with the view I'm lost
In wonder, love, and praise."

STEAM NAVIGATION.—We might have been apt to suppose, that the chemical experiments that were first made to demonstrate the force of *Steam* as a mechanical agent, could have little relation to the objects of Religion, or even to the comfort of human life and society. Yet it has now been applied to the impelling of ships and large boats along rivers and seas, in opposition to both wind and tide, and with a velocity which, at an average, exceeds that of any other mode of conveyance by

---

diameter, 5½ inches thick at the edges, and 5 inches at the center, and its weight is about *three tons*. Its composition is copper and tin—126 parts of copper to 57½ of tin. The price of the copper alone is reckoned at about £100. By grinding and polishing, its thickness was reduced ⅛ or 1-10 inch. It is formed into a telescope of 50 feet focal length. The casting of this immense speculum, with all the operations connected with it, were accomplished without any accident, and with a degree of success beyond expectation. This speculum has a reflecting surface of 4071 square inches, while that of Herschel's 40 feet telescope had only 1811 square inches on its polished surface; so that the quantity of light reflected from this speculum is considerably more than double that of Herschel's largest reflector. This certainly forms one of the most noble and splendid instruments of the kind that have ever been constructed,—and it is not improbable that by its assistance, further interesting discoveries may be made in the regions of the stars.

[*] See Appendix, Note X.

water. And we have no reason to believe that this invention has hitherto attained its highest state of perfection; but that it is still susceptible of such improvements, both in point of expedition and of safety, as may render it by far the most comfortable and speedy conveyance between distant lands, for transporting the volume of inspiration, and the heralds of the gospel of peace, to "the ends of the earth." By the help of his compass, the mariner is enabled to steer his course in the midst of the ocean, in the most cloudy days, and in the darkest nights, and to transport his vessel from one end of the world to another. It now only remains, that navigation be rendered safe, uniform, and expeditious, and not dependent on adverse winds or the currents of the ocean; and there is every reason to expect, as the art of propelling vessels by the force of steam proceeds toward perfection, that these desirable objects will be fully attained. Even at present, as the invention now stands, were a vessel fitted to encounter the waves of the Atlantic, constructed of a proper figure and curvature, with a proper disposition of her wheels, and having room where fuel can be stowed in sufficient quantity for the voyage, at the rate of ten miles an hour, she would pass from the shores of Britain to the coast of America, in less than thirteen days;—and, even at eight miles an hour, the voyage could be completed in little more than fifteen days: so that intelligence might pass and repass between the eastern and western Continents within the space of a single month—a space of time very little more than was requisite, eighty years ago, for conveying intelligence between Glasgow and London. The greatest distance at which any two places on the globe can lie from each other is about 12,500 miles; and therefore if a direct portion of water intervene between them, this space could be traversed in fifty-four or sixty days.* And, if the isthmus of Panama which connects North and South America, and the isthmus of Suez, which separates the Mediterranean from the Red sea, were cut into wide and deep canals (which we have no doubt will be accomplished as soon as civilized nations have access to perform operations in these territories), every country in the world could then be reached from Europe, in nearly a direct line; or, at most, by a gentle curve, instead of the long, and dangerous, and circuitous route which must now be taken, in sailing for the eastern parts of Asia, and the north-western shores of America. By this means, eight or nine thousand miles of sailing would be saved in a voyage from England to Nootka Sound, or the peninsula of California; and more than six thousand miles in passing from London to Bombay in the East Indies; and few places on the east would be farther distant from each other by water than 15,000 miles; which space might be traversed at the rate stated in the preceding note, in a period of about fifty days.*

But we have reason to believe, that when this invention, combined with other mechanical assistances, shall approximate nearer to perfection, a much more rapid rate of motion will be effected; and the advantages of this, in a religious, as well as in a commercial point of view, may be easily appreciated; especially at the present period, when the Christian world, now aroused from their slumbers, have framed the grand design of sending a Bible to every inhabitant of the globe. When the empire of the Prince of Darkness shall be shaken throughout all its dependencies, and the nations aroused to inquire after light, and liberty, and divine knowledge—intelligence would thus be rapidly communicated over every region, and between the most distant tribes. "Many would run to and fro, and knowledge would be increased." The ambassadors of the Redeemer, with the Oracles of Heaven in their hands, and the words of salvation in their mouths, would quickly be transported to every clime, "having the everlasting gospel to preach to every nation, and kindred, and tongue, and people."

Air Balloons.—Similar remarks may be applied to the *invention of air balloons*. We have heard of some pious people who have mourned over such inventions, and lamented the folly of mankind in studying their construction and witnessing their exhibition. Such dispositions generally proceed from a narrow range of thought and a contracted view of the Divine economy and arrangements in the work of redemption. Though the perversity of mankind has often applied useful inventions to foolish and even to vicious purposes, yet this forms no reason why such inventions should be decried; otherwise the art of printing and many other useful arts might be regarded as inimical to the human race. We have reason to believe that air balloons may yet be brought to such perfection as to be applied to purposes highly beneficial to the progress of the human mind, and subservient, in some degree, for effecting the purposes of Providence in the enlightening and renovation of mankind. For this purpose, it is only requisite that some contrivance, or chemical or mechanical principles, be suggested, analogous to the sails or rudder of a ship, by which they may be moved in any direction, without being directed solely by the course of the wind; and there can be little doubt that such a contrivance is *possible* to be effected. It requires only suitable encouragement to be given to ingenious experimental philosophers, and a sufficient sum of money to enable them to prosecute their experiments on an extensive scale. To the want of such prerequisites it is chiefly owing that the hints on this subject, hitherto suggested, have either failed of success or have never been carried into execution. A more simple and expeditious process for filling balloons has lately been effected,—the use of the *parachute*, by which a person may detach himself from the balloon, and descend to the earth, has been successfully tried,—the lightning of heaven has been drawn from the clouds, and forced to act as a mechanical power in splitting immense stones to pieces,—the atmosphere has been analyzed into its component parts, and the wonderful properties of the ingredients of which it is composed exhibited in their separate state;—and why then should we consider it as at all improbable that the means of producing a horizontal direction in aerial navigation may soon be discovered? Were this object once effected, balloons might be applied to the purposes of surveying and exploring countries hitherto inaccessible, and of conveying the messengers of divine mercy to tribes of our fellow-men, whose existence is as yet unknown.

---

* The above statements were written in 1823, when the first edition of this work was published, and were then considered as somewhat extravagant anticipations, which were scarcely expected to be realized, at least in the present age. It is but within the last few years that one of our most distinguished philosophers and engineers, Dr. Lardner, denounced the scheme of attempting to cross the Atlantic by means of steam as an enterprise altogether impracticable. But the navigation of the Atlantic, by means of steam vessels, for several years past, has been regular, and almost as common as with ordinary sailing vessels;—and the rate of motion has been even greater than what we anticipated. The *Great Western* was among the first steam vessels that crossed the Atlantic from Britain to America, in 1838, and accomplished the voyage, in safety, in about 13 days, having on board above a hundred passengers. Since that period other vessels, as the Acadia, Britannia, Caledonia, Columbia, etc., have regularly performed voyages to and from the shores of America and Great Britain, and, except in the case of the *President*, they have all been accomplished without any serious accidents,—so that, the practicability and the utility of steam navigation across the ocean may now be considered as fully established. Voyages by steam are likewise now regularly performed to Lisbon, Cadiz, and along the Mediterranean, as far as Alexandria, and from Bombay to Suez along the Arabian and the Red sea—and therefore we have reason to expect that, in the course of a very few years every sea and ocean on the surface of the globe will be traversed by steam vessels, promoting a rapid intercourse between all the nations, tribes, and families of the earth.—The rate of motion at which such vessels are impelled across the Atlantic may be deduced from the following facts. The first voyage of the *Britannia*, which sailed on the 4th July, 1840, from Liverpool to Halifax, was accomplished in 12 days, 10 hours; and her return homeward occupied only 10 days. The outward voyage of the *Columbia*, which sailed from Liverpool, May 19, 1842, was performed in 11 days, 22 hours, and her voyage home from Halifax in 9 days, 17 hours. Her voyage from Boston, in the United States, including a stoppage of 6 hours at Halifax to land and take in passengers and mails, was performed in 11 days, 6 hours, from that city to Liverpool. Of 28 voyages of the Acadia, Britannia, Caledonia, and Columbia, performed in the years 1840, 1841, and 1842, between Liverpool and Halifax—the average time employed in the passage is found to be as follows: *Outward* voyage to Halifax 13 days, 6 hours:—*Homeward* to Liverpool 11 days, 6 hours. It thus appears that intelligence may now pass and repass between Britain and the continent of America in 23 or 24 days, or little more than 3 weeks, so that it is possible a person might receive an answer to a communication sent to America in less than 3½ weeks. At this rate, 15,000 miles—or the greatest distance between any two places on the globe by water, might be traversed in about 50 days.

* See Appendix, Note XI.

We are certain that every portion of the inhabited world must be thoroughly explored, and its inhabitants visited, before the salvation of God can be carried fully into effect; and for the purpose of such explorations, we must of course resort to the inventions of human genius in art and science. Numerous tribes of the sons of Adam are, doubtless, residing in regions of the earth with which we have no acquaintance, and to which we have no access by any of the modes of conveyance presently in use. More than one half of the interior parts of Africa and Asia, and even of America, are wholly unknown to the inhabitants of the civilized world. The vast regions of Chinese Tartary, Thibet, Siberia, and the adjacent districts; the greater portion of Africa, and the continent of New Holland; the extensive isles of Borneo, Sumatra, New Guinea, and Japan, the territory of the Amazons, and the internal parts of North America, remain, for the most part, unknown and unexplored. The lofty and impassable ranges of mountains, and the deep and rapid rivers, which intervene between us and many of those regions, together with the savage and plundering hordes of men and the tribes of ravenous beasts through which the traveler must push his way—present to European adventurers barriers which they cannot expect to surmount, by the ordinary modes of conveyance, for a lapse of ages. But, by balloons constructed with an apparatus for directing their motions, all such obstructions would at once be surmounted. The most impenetrable regions, now hemmed in by streams and marshes and lofty mountains, and a barbarous population, would be quickly laid open; and cities and nations, lakes and rivers, and fertile plains, to which we are now entire strangers, would soon burst upon the view. And the very circumstance that the messengers of peace and salvation *descended upon such unknown tribes from the region of the clouds*, might arouse their minds and excite their attention and regard to the message of divine mercy which they came thither to proclaim.* Such a scene (and it may probably be realized) would present a literal fulfillment of the prediction of "*angels flying through the midst of*" the aerial "*heaven*, having the everlasting gospel to preach to them that dwell upon the earth, and to every kindred and nation."

That the attention of the philosophical world is presently directed to this subject, and that we have some prospect of the views above suggested being soon realized, will appear from the following notice, which some time ago made its appearance in the London scientific journals:—A prize being offered for the discovery of a horizontal direction in aerostation, M. Mingreli of Bologna, M. Pietripoli of Venice, and M. Lember of Nuremberg, have each assumed the merit of resolving this problem. It does not appear that any one of these has come forward to establish, by practical experiment, the validity of his claim; but a pamphlet has lately been reprinted in Paris (first printed at Vienna) on this subject, addressed to all the learned societies in Europe. The following passage appears in the work: "'Professor Robertson proposes to construct an aerostatic machine, 150 feet in diameter, to be capable of raising 72,954 kilograms, equivalent to 149,037 lbs. weight (French). To be capable of conveying all necessaries for the support of sixty individuals, scientific characters, to be selected by the academicians, and the aerial navigations to last for some months, exploring different hights and climates, etc., in all seasons. If, from accident or wear, the machine, elevated above the ocean, should fail in its functions, to be furnished with a ship that will insure the return of the aeronauts.'"

Of late years, the attention of several scientific gentlemen has been directed to the improvement of aerial navigation, and it is the opinion of many that the problem of giving to balloons a horizontal direction has been in some measure solved. About the year 1837 some plans of this description were laid before a committee of the Royal Society, and an association was attempted to be formed for exploring the continent of Africa by means of a large balloon which was to be constructed for this special purpose; but after the projectors had proceeded a certain length, the scheme was allowed to drop, for want of patronage and support. In the year 1840, Mr. Green, the most celebrated aeronaut of modern times, who has performed several hundreds of aerial voyages, proposed making a voyage in a balloon from the American to the European continent, across the Atlantic. In order to convince the scientific public of the practicability of his propelling or directing a balloon, causing it to ascend or descend, without discharging either gas or ballast—and in a tranquil atmosphere, to move horizontally and *in any direction* —he commenced a series of important experiments, at the *Polytechnic Institution*, London, which excited considerable attention, and created a great sensation among the curious in scientific matters. The machinery made use of by Mr. G. consisted of two *propellers* attached to a spindle, a *rudder*, a *guide-line*, and several *appendages*. The propeller appears to have been somewhat like two sails of a windmill which were whirled round with a rotatory motion, and which were intended to produce an effect both on the horizontal progress of the balloon and likewise in elevating and depressing it.* The practicability of Mr. Green's plans appears to have been admitted by many scientific gentlemen; and although he has never yet attempted his daring aerial excursion across the Atlantic, yet it is well known that he performed, along with Mr. Mason, in the great Nassau balloon, an aerial voyage from England across the German sea to Weilburg in Germany, one of the most daring and extensive voyages hitherto attempted, and which was accomplished without the least danger. The possibility of an aerial excursion across the Atlantic may perhaps be admitted; but its expediency, in the meantime, may justly be called in question.

---

* In this point of view, we cannot but feel the most poignant regret at the conduct of the Spaniards, after the discovery of America, toward the natives of that country. When those untutored people beheld the ships which had conveyed Columbus and his associates from the eastern world, the dresses and martial order of his troops, and heard their music, and the thunder of their cannon, they were filled with astonishment and wonder at the strange objects presented to their view; they fell prostrate at their feet, and viewed them as a superior race of men. When *Cortez* afterward entered the territories of Mexico, the same sentiments of reverence and admiration seemed to pervade its inhabitants. Had pure Christian motives actuated the minds of these adventurers, and had it been their ruling desire to communicate to those ignorant tribes the blessings of the Gospel of peace, and to minister to their external comfort, the circumstance now stated would have been highly favorable to the success of missionary exertion, and would have led them to listen with attention to the message from Heaven. But, unfortunately for the cause of religion, treachery, lust, cruelty, selfishness, and the cursed love of gold, predominated over every other feeling, affixed a stigma to the Christian name, and rendered them curses instead of blessings, to that newly discovered race of men. It is most earnestly to be wished, that, in future expeditions in quest of unknown tribes, a few intelligent and philanthropic missionaries were appointed to direct the adventurers in their moral conduct and intercourses with the people they visit, in order that nothing inconsistent with Christian principle make its appearance The uniform manifestation of Christian benevolence, purity, and rectitude, by a superior race of men, would win the affections of a rude people far more effectually than all the pomp and ensigns of military parade.

As the invention now stands, the balloon, under the direction of such an experienced aeronaut as Mr. Green, might be rendered subservient to many important purposes, particularly in taking a general survey of unknown countries. Suppose a balloon, properly equipped for the purpose, were to be elevated either on the eastern or the western shores of Africa, so as to pass nearly over the central parts of that continent,—by taking advantage of the monsoons, or trade-winds, which blow for a certain period in the same direction—the general aspect and character of this country, with which we are at present so little acquainted, might be laid open to view, at least as to its more prominent and general features. The extent of its lakes—the direction and magnitude of its rivers—the ranges of mountains with which it is diversified—its deserts, forests, and cultivated fields—the positions and magnitude of its cities—the characteristics of its inhabitants, and the probable amount of population—with several other particulars—might all be deduced by an intelligent aeronaut, when passing across such a country at a proper elevation, beside having an opportunity of performing a variety of electric, magnetic, and other scientific experiments, for enlarging our knowledge of the principles and processes of nature. In the same manner the Chinese Empire—of which we know so little—might be extensively surveyed, and our knowledge of that interesting and populous region of the globe rendered more definite and expansive. In both these cases, and several others, the course of the periodical winds might be rendered subservient to the success of the enterprise.

Should any one be disposed to insinuate, that the views now stated on this subject are chimerical and fallacious, I beg leave to remind them, that not more than twenty years ago, the idea of a large vessel, without oars or sails, to be navigated against the wind with the rapidity of twelve miles an hour, would have been considered as next to an impossibility, and a mere fanciful scheme, which could never be realized. Yet we now behold such vehicles transporting whole villages to the places of their destination, with a degree of ease, comfort, and expedition, formerly unknown, and even crossing in safety the wide Atlantic ocean. And little more than fifty years have elapsed, since it would have been viewed as still more chimerical to have broached the idea, that a machine might be constructed, by which human beings might ascend more than two miles above the surface of the earth, and fly through the region of the clouds at the rate of seventy miles an hour, carrying along with them books, instruments, and provisions. Yet both these schemes have been fully realized, and, like many other inventions of the human intellect, are doubtless intended to subserve some important ends in the economy of Divine Providence.*

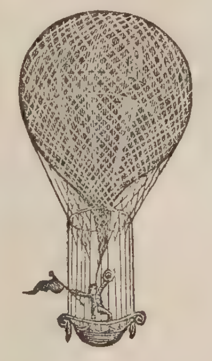
---

* The reader will find an account of Mr. Green's experiments in the *Polytechnic Journal* for January and February, 1840, and likewise in the No. of the *Mirror* for April, etc., 1840, vol. 35, with an Engraving of the proposed balloon.

* Balloons were first constructed in the year 1783, by Messts. S. & J. Montgolfier, paper manufacturers at Annonay, in France. A sheep, a cock, and a duck, were the first animals ever carried up into the air by these vehicles. At the end of their journey, they were found perfectly safe and unhurt, and the sheep was even feeding at perfect ease. The first *human* being who ascended into the atmosphere in one of those machines, was M. Pilatre de Rozier. This adventurer ascended from amidst an astonished multitude assembled in a garden in Paris, on the 15th October, 1783, in a balloon, whose diameter was 48 feet, and its hight about 74; and remained suspended above the city about four hours. M. Lunardi, an Italian, soon after astonished the people of Scotland and England, by his aerial excursions, Dr. G. Gregory gives the following account of his first ascent:—"I was myself a spectator of the flight of Lunardi, and I never was present at a sight so interesting and sublime. The beauty of the gradual ascent, united with a sentiment of terror on account of the danger of the man, and the novelty and grandeur of the whole appearance, are more than words can express. A delicate woman was so overcome with the spectacle, that she died upon the spot as the balloon ascended; several fainted; and the silent admiration of the anxious multitude was beyond anything I had ever beheld."

Balloons have generally been made of varnished silk, and of the shape of a globe or a spheroid (see fig. 28), from thirty to fifty feet in diameter. They are filled with hydrogen gas, which, as formerly stated, is from twelve to fifteen times lighter than common air: and they rise in the atmosphere on the same principle as a piece of cork ascends from the bottom of a pail of water. The aerial travelers are seated in a basket below the balloon, which is attached to it by means of cords.—The *Parachute* (see fig. 29) is an invention, by which the voyager, in cases of alarm, may be enabled to desert his balloon in mid-air, and descend with

Fig. 28.



Acoustic Tunnels.—By means of the inventions just now adverted to, when brought to perfection, mankind may be enabled to transport themselves to every region of the globe, with a much greater degree of rapidity than has hitherto been attained. By the help of the microscope, we are enabled to contemplate the invisible worlds of life, and by the telescope we can penetrate into regions far beyond the range of the unassisted eye. By the arts of Writing and Printing we can communicate our sentiments, after a certain lapse of time, to every quarter of the world. In the progress of human knowledge and improvement, it would obviously be of considerable importance, *could we extend the range of the human voice*, and communicate intelligence to the distance of a thousand miles, in the course of two or three hours; or could we hold an occasional conversation with a friend at the distance of twenty or thirty miles. From experiments which have lately been made, in reference to the conveyance of sound, we have some reason to believe that such objects may not be altogether unattainable. It has been long known that wood is a good conductor of sound. If a watch be laid on the one end of a long beam of timber, its beating will be distinctly heard, on applying the ear to the other end, though it could not be heard at the same distance through the air. In "Nicholson's Philosophical Journal" for February 1803, Mr. E Walker describes a simple apparatus, connected with a speaking trumpet, by means of which, at the distance of 17½ feet, he held a conversation with another in whispers, too low to be heard through the air at that distance. When the ear was placed in a certain position, the words were heard as if they had been spoken by an invisible being within the trumpet. And what rendered the deception still more pleasing, the words were more distinct, softer, and more musical, than if they had been spoken through the air.

About the year 1750, a merchant of Cleves, named Jorissen, who had become almost totally deaf, sitting one day near a harpsichord, while some one was playing, and having a tobacco-pipe in his mouth, the bowl of which rested accidentally against the body of the instrument, he was agreeably and unexpectedly surprised to hear all the notes in the most distinct manner. By a little reflection and practice, he again obtained the use of this valuable sense: for he soon learned, —by means of a piece of hard wood, one end of which he placed against his teeth, while another person placed the other end on his teeth,—to keep up a conversation, and to be able to understand a whisper. In this way, two persons who have stopped their ears may converse with each other, when they hold a long stick, or a series of sticks, between their teeth, or rest their teeth against them. The effect is the same, if the person who speaks rest the stick against his throat or his breast, or when one rests the stick which he holds in his teeth against some vessel into which the other speaks; and the effect will be the greater, the more the vessel is capable of tremulous motion. These experiments demonstrate the facility with which the softest whispers may be transmitted. Water, too, is found to be a good conductor of sound. Dr. Franklin assures us, that he has heard under water, at the distance of half a mile, the sound of two stones struck against each other. It has also been observed, that the *velocity* of sound is much greater in solid bodies, than in the air. By a series of experiments, instituted for the purpose of determining this point, Mr. Chladni found that the velocity of sound, in certain solid bodies, is 16 or 17 times as great as in air.

But what has a more particular bearing on the object hinted at above, is the experiments, lately made by M. Biot, "on the transmission of sound through solid bodies, and through air, in very long tubes." These experiments were made by means of long cylindrical pipes, which were constructed for conduits and aqueducts, to embellish the city of Paris. With regard to the *velocity* of sound, it was ascertained that "its transmission through cast iron is 10½ times as quick as through air. The pipes by which he wished to ascertain at what distance sounds are audible were 1039 yards, or nearly five furlongs in length. M. Biot was stationed at the one end of this series of pipes, and Mr. Martin, a gentleman who assisted in the experiments, at the other. They heard the lowest voice, so as perfectly to distinguish the words, and to keep up a conversation on all the subjects of the experiments. "I wished," says M. Biot, "to determine the point at which the human voice ceases to be audible, but could not accomplish it: words spoken as low as when we whisper a secret in another's ear were heard and understood; so that not to be heard, there was but one resource,

---

out injury to the ground. They resemble an umbrella, but are of far greater extent. With one of these contrivances, twenty-three feet in diameter, M. Garnerin, having detached himself from his balloon, descended from a hight of more than 4000 feet, and landed without shock or accident.

The above representation (fig. 28) exhibits a view of Mr. Green's balloon, when he ascended from St. James's Park, London, on the occasion of the coronation of George IV. The form of the balloon was nearly of the shape of a pear; it was composed of stripes of variegated silk; and over this was thrown an envelope of net-work, which, passing down, served as a support to the car in which the aeronaut was placed. It may give the reader who has never seen a balloon, a general idea of its form and of the mode in which aerial navigation is performed.

Fig. 29.

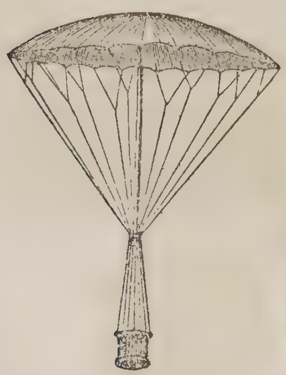


Fig. 30.

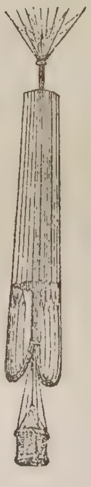


Figs. 29 and 30 represent the parachute of M. Garnerin, and the apparatus connected with it. In fig. 30 is shown a cylindrical box, about 3 feet in hight and 2 in diameter, which was attached by a straight pole, to a truck or disc at the top, and from this was suspended a large sheet of linen somewhat similar to an umbrella. M. Garnerin stood in the box, and the form the machine assumed on his descent is shown in fig. 29. When first cut from the balloon, it descended with great velocity, and those who witnessed its progress considered his destruction inevitable; but after a few seconds, the canvas opened and the resistance was so great, that the apparatus diminished in its speed, until, on its arrival near the earth, it was not greater than would have resulted from leaping a hight of two feet.

that of not speaking at all.—This mode of conversing with an invisible neighbor is so singular, that we cannot help being surprised, even though acquainted with the cause. Between a question and answer, the interval was not greater than was necessary for the transmission of sound. For Mr. Martin and I, at the distance of 1039 yards, this time was about 5½ seconds." Reports of a pistol fired at one end occasioned a considerable explosion at the other. The air was driven out of the pipe with sufficient force to give the hand a smart blow, to drive light substances out of it to the distance of half a yard, and to extinguish a candle, though it was 1039 yards distant from the place where the pistol was fired. A detailed account of these experiments may be seen in *Nicholson's Phil. Jour. for October*, 1811.—Don Gautier, the inventor of the Telegraph, suggested also the method of conveying articulate sounds to a great distance. He proposed to build horizontal tunnels, widening at the remoter extremity, and found that, at the distance of 400 fathoms, or nearly half a mile, the ticking of a watch could be heard far better than close to the ear. He calculated, that a series of such tunnels would convey a message 900 miles in an hour.

From the experiments now stated, it appears highly probable that sounds may be conveyed to an indefinite distance. If one man can converse with another at the distance of nearly three quarters of a mile, *by means of the softest whisper*, there is every reason to believe that they could hold a conversation at the distance of 30 or 40 miles, provided the requisite tunnels were constructed for this purpose. The latter case does not appear more wonderful than the former. Were this point fully determined by experiments conducted on a more extensive scale, a variety of interesting effects would follow, from a practical application of the results. A person, at one end of a large city, at an appointed hour, might communicate a message, or hold a conversation with his friend, at another; friends in neighboring, or even in distant towns, might hold an occasional correspondence by articulate sounds, and recognize each other's identity by their tones of voice. In the case of sickness, accident, or death, intelligence could thus be instantly communicated, and the tender sympathy of friends immediately exchanged. A clergyman sitting in his own room, in Edinburgh, were it at any time expedient, might address a congregation in Musselburgh or Dalkeith, or even in Glasgow. He might preach the same sermon to his own church, and the next hour to an assembly at forty miles distant. And surely there could be no valid objection to trying the effect of an *invisible preacher* on a Christian audience. On similar principles, an apparatus might be constructed for augmenting the strength of the human voice, so as to make it extend its force to an assembled multitude, composed of fifty or a hundred thousand individuals; and the utility of such a power, when the mass of mankind are once thoroughly aroused to attend to rational and religious instruction, may be easily conceived. In short, intelligence respecting every important discovery, occurrence, and event, might thus be communicated, through the extent of a whole kingdom, within the space of an hour after it had taken place.

Let none imagine that such a project is either chimerical or impossible. M. Biot's experiment is decisive, so far as it goes; that the *softest whisper*, without any diminution of its intensity, may be communicated to the distance of nearly three quarters of a mile; and there is nothing but actual experiment wanting to convince us, that the ordinary tones of the human voice may be conveyed to at least twenty times that distance. We are just now acting on a similar principle in distributing illumination through large cities. Not above 40 or 50 years ago, the idea of lighting our apartments by an invisible substance, produced at ten miles distance, would have been considered as chimerical, and as impossible to be realized, as the idea of two persons conversing together, by articulate sounds, at such a distance. It appears no more wonderful, that we should be able to *hear* at a distance of five or six miles, than that we should be enabled to *see* objects at that distance by the telescope, as distinctly as if we were within a few yards of them. Both are the effects of those principles and laws which the Creator has interwoven with the system of the material world; and when man has discovered the mode of their operation, it remains with himself to apply them to his necessities. What the telescope is to the eye, acoustic tunnels would be to the ear; and thus those senses on which our improvement in knowledge and enjoyment chiefly depends, would be gradually carried to the utmost perfection of which our station on earth will permit. And as to the *expense* of constructing such communications of sound, the *tenth part* of the millions of money expended in the twenty-one years' war in which we were lately engaged, would, in all probability, be more than sufficient for distributing them, in numerous ramifications, through the whole island of Great Britain. Even although such a project were partially to fail of success, it would be a far more honorable and useful national undertaking, than that which now occupies the attention of the despots on the continent of Europe, and might be accomplished with far less expenditure, either of blood or of money. Less than the fourth part of a million of pounds would be sufficient for trying an experiment of this kind, on an extensive scale; and such a sum is considered as a mere *item*, when fleets and armies are to be equipped for carrying destruction through sea and land. When will the war-madness cease its rage! When will men desist from the work of destruction, and employ their energies and their treasures in the cause of human improvement? The most chimerical projects that were ever suggested by the most enthusiastic visionary, are not half so ridiculous and *degrading* to the character of man, as those ambitious and despotic schemes, in which the powers of the earth in all ages have been chiefly engaged.—But on this topic it is needless to enlarge, until more extended experiments shall have been undertaken.

Electric Telegraphs.—The electric and galvanic powers have been lately employed in transmitting telegraphic signals through wires to any assignable distance. More than 13 years ago, Sir H. Davy, Dr. Ritchie, and several others, formed the idea of constructing an electrical telegraph; and in 1837, the model of an apparatus for this purpose was exhibited by Mr. Alexander to the Society of Arts, in Edinburgh. Professor Wheatstone, of King's College, London, lately made considerable improvements in the construction of these instruments, particularly in the reduction of the number of wires requisite in such an apparatus.—The general principle on which such an operation is founded, is, that of causing the galvanic current to deflect a needle poised on a center; and, by certain arrangements, the needle is made to point to any letter on a dial plate. Professor Wheatstone's apparatus consists of two small galvanic troughs or batteries; four lengths of copper wire, an object resembling a brass clock, with a small opening or dial on the surface sufficient to show a single letter at a time; close by this an upright pivot of brass about 3 inches high, having a circular top inscribed with the letters of the alphabet all round, and from each letter a spike pointing outward. The whole stands on a table, except the wires, which, being four miles in length, and warped in numberless convolutions through the vaults of the college, are observable only at their extremities, in connection with the apparatus. The galvanic property generated in the batteries is made to proceed along the wires, and in its passage to affect the mechanism in the apparatus now described. The letters can be exposed at the rate of two in every second. A gentleman who witnessed its performance, says, "A lady turning the capstan with her finger, brought into view the word LONDON, in the time it could be uttered letter by letter, although the idea had to travel through 4 miles of wire."

The capabilities of the principle of this instrument have been tested on the line of the Great Western Railway. In September, 1839, the wires of the electric telegraph were carried to Drayton, a distance of 15 miles from London, and the experiment was attended with complete success. To such a question as the following,—"How many passengers started from Drayton by the 10 o'clock train?" the answer could be transmitted from the terminus to Drayton and back in less than two minutes. The wires of communication pass through a hollow iron tube about an inch and a half in diameter, which is fixed about 6 inches above the ground, parallel with the railway, and about two or three feet distant from it; and it is probable that, by this time, they have been carried forward the whole length of the railway, which extends to Bristol, a distance of 117 miles.

In transmitting the electric influence through wires—however great the distance—the time occupied in the transmission is nearly the same, for there is reason to believe that it flies with the same velocity as *light*, whose rate of motion is nearly two hundred thousand miles in a second. Were wires extended from Britain to China, on the one hand, and to America, on the other, intelligence could be transmitted to those regions in as short a time as in conveying it across a garden or a large hall. It is hard to say to what extent signals may, in point of fact, be communicated in this way, in the course of the improvements which are now going forward. Were the nations of Europe living in perfect amity and peace, and in a friendly communication with each other, telegraphs of this description might be ramified throughout the whole extent of the continent, from north to south, and from east to west; and the expense of constructing them would be but a slight *item*, compared with the sums expended in useless parade, in warfare, and in schemes of folly. They might, at any rate, be spread in different directions throughout the island of Great Britain, or, at least along the great thoroughfares leading toward the metropolis; and offices established at different stages for communicating and receiving intelligence—with prices affixed corresponding to the distance from which the intelligence is conveyed. It is easy to see that such a rapid communication of intelligence—in numerous instances, which our limits will not permit us to specify—might be highly beneficial to the interests of general society.

Thus it appears that the same physical principle or agent which produces the forked and fire-ball lightnings, and all the dread phenomena of a violent thunder-storm—which rends in pieces the sturdy oak, and strikes whole herds of cattle lifeless to the ground—which displays its terrific energy in the awful phenomena of volcanoes, hurricanes, and earthquakes—that the same agent is now, by human art, rendered subservient to the conveyance of swift intelligence from one place to another, and to many other useful purposes in society—and, perhaps, ere long, its destructive energies may be completely counteracted by the contrivances of human ingenuity, when its nature and properties, and its mode of operation, shall be more completely unfolded. And, it is not unlikely, as the investigations of philosophy proceed, that new principles may be discovered in the system of nature, more wonderful than any that have yet come within the reach of our knowledge, which may both enlarge our views of the operations of the Creator, and be applicable to manifold beneficial purposes in the economy of human society.

RAILWAYS.—The mode of traveling by means of railways, which has been lately introduced into Great Britain and many other countries, is an improvement no less wonderful and beneficial to society than that of steam navigation, and promises to promote the general intercourse of mankind, and the conveyance of political and commercial intelligence to an extent and with a velocity which former ages could never have anticipated.

It appears that, so early as the year 1676, coals were carried from the mines near Newcastle-upon-Tyne to the banks of the river, by laying rails of timber exactly straight and parallel, on which large carts, with four rollers fitting the rails, and drawn by horses, could convey at once four or five caldrons of coals. About a century afterward, an *iron* railroad was constructed at the Sheffield colliery. But the first railway resembling those now in use, as a public thoroughfare for the conveyance of goods and passengers, was the "Stockton and Darlington Railway," which was completed only in 1825, and was the first which was attended with complete success. Several years, however, elapsed before steam locomotive engines were adopted. This noble triumph of art, in the swift conveyance of goods and passengers, was first practically exhibited at the opening of the "Liverpool and Manchester Railway," on the 15th September, 1830, when it was found that trains of carriages could be conveyed at the rate of 25 or 30 miles an hour. Since this period, railways have been distributed throughout almost all the populous districts of our country.

The rails on which the wheels of the engines and carriages move are all made of iron. At first it was supposed that malleable iron rails were to be preferred; but it is now understood that *cast*-iron rails, if properly made, will endure all the tear and wear to which they are in general subjected. Each individual rail is about 12 feet in length, and 6 inches in depth at the two ends. Their thickness is about one inch, and the upper surface on which the wheel is to run, about two inches, so as to project laterally like the cross top of the letter T. They are pinned together at their extremities, and are supported at intervals of every three feet. The supporters on some lines of railroad consist of *stone* sleepers sunk into the ground; but it is generally admitted that *transverse bars of wood* sunk in the ground are preferable, as both lines of rail are thus kept from separating or shifting, and as stone sleepers present too unyielding a base to the rolling of the wheels. In order to keep the wheels on the rails, they are furnished with thin edges, which dip or the outside. The wheels of the locomotive have a diameter of about 4 feet; the diameter for the wagon or carriage-wheels is generally from 30 to 36 inches. The locomotive is now generally placed upon six wheels; the front and hind pair being smaller than those in the middle; these middle ones being the wheels upon which, by the action of cranks from the engine, the whole mass is propelled. A chimney rises in front, and a standing place behind is allotted for the engineer, who conducts and regulates the machine. The barrel-like object next the engineer consists of a furnace or fire-box, and the heat generated in it by the consumption of coke, is conducted thence through a great number of tubes in the cylinder, and finally escapes at the chimney. By means of lever handles affecting the mechanism, the engineer can at pleasure produce or stop the motion as effectually as a coach-driver could set off, or arrest the progress of his horses. Immediately behind the locomotive is a carriage called the *tender*, which is loaded with fuel, and has a tank round its sides containing water. The weight of a locomotive, supplied with its proper quantity of water and fuel, is about 12 tons. When filled with water and fuel, the tender weighs about 7 tons; it can carry 700 gallons of water, and eight hundred weight of coke—which will form a supply for a trip of 30 or 40 miles.

The *expenses* incurred in the construction and management of railways are very considerable.—All inequalities of surface in the line proposed must be removed—low parts filled up by embankments—high parts reduced—eminences which it would be impossible or too expensive to level, must be perforated by *tunnels*, and over dells and rivers viaducts require to be thrown, consisting, in some cases, of numerous arches. Beside, a previous survey must be made—the land over which it is to pass must be purchased sometimes at an exorbitant price—an act of parliament must be procured—and various petty and vexatious oppositions, arising from the avarice and obstinacy of landed proprietors, must be overcome, which not unfrequently add to all the other expenses. It has been estimated that, at an average, £30,000 per mile may be considered as a moderate outlay in the construction of railways throughout most parts of Great Britain. The London and Birmingham railway—a line extending 112 miles—cost much more; its whole expense amounted to several millions of pounds. The least expensive railway we have yet heard of, is that between Dundee and Arbroath, the average expense of which per mile is estimated not to exceed £8000. The cost of a locomotive is about £1700, and it seldom wears longer than two years without undergoing an extensive repair. Ordinary locomotives evaporate 77 cubic feet of water per hour; those on the Great Western railway about 200 cubic feet. The evaporation of one cubic foot per hour produces a mechanical force of nearly 2 horse power; consequently we may ascertain the power of a locomotive by multiplying by 2 the number of cubic feet which it evaporates in an hour. An ordinary sized locomotive exerts a power of 150 horses; a horse upon a common road cannot draw for any length of time more than 15 hundred weight, while on a railway it will pull with equal ease ten tons, which is thirteen times the amount; and therefore the power of a locomotive such as is usually employed, is equal to a draught of 1462 tons.

The railways in most parts of Britain consist of two tracks, suitable for trains going in opposite directions; in America, Belgium, and other places, they consist generally of but one track. On most of the lines there are *slow* trains for goods and 2d class passengers—*fast* trains, taking only 1st and 2d class carriages—some lines have *mail* trains which proceed at more than usual speed, and stop at fewer places by the way. The 1st class carriages are covered—the 2d class carriages are open at the sides—and the 3d class carriages are entirely open, in some of which the passengers are obliged to *stand* during the journey, arising from a principle of avarice in the proprietors, and a foolish design of compelling, if possible, the lower classes to select the 1st and 2d class carriages. The carriages for goods are open on trucks, on which the articles are piled; and for cattle there are open trucks with a railing round the sides. All the carriages in a train—amounting in some cases to twenty or thirty—are linked one to the other by strong iron hooks, and to prevent them from shocks against each other, the various carriages are provided with projecting rods on springs cushioned at the outer extremities. From one hundred to a thousand passengers are thus conveyed, at one time, from one city or town to another; and it is a universal rule that no servant or officer shall on any account take a fee from passengers, on pain of instant dismissal.

About 50 railways have been completed in the United Kingdom of Great Britain up to 1842.—The following are some of the principal lines—in England—The Liverpool and Manchester Railway, 32 miles in length, which cost £46,000 per mile; the London and Birmingham Railway, 112½ miles long, connecting the metropolis with the center of England, in which are several long and expensive tunnels, and which cost above £50,000 per mile; the Grand Junction Railway, 79 miles in length, connecting the London and Birmingham line to that of Liverpool and Manchester, and also to a railway proceeding northward to Lancaster, which cost £21,859 per mile, forming an important thoroughfare obliquely across the country; the Manchester and Leeds Railway, 50 miles in length; the Midland Counties, North Midland and Great North of England railways, connecting the great seats of trade in Northumberland, Durham, Yorkshire, and Derbyshire, with the London and Birmingham line; the Newcastle and Carlisle Railway, 61 miles long; the Great Western Railway, 117 miles long; which cost £53,241 per mile, and which connects London with Bristol and with smaller tributary lines opening up the west of England; the South-Western Railway, 77 miles long, connecting London with Southampton.—The principal lines of railway in *Scotland* are—The Edinburgh and Glasgow Railway, about 46 miles long, on which are several beautiful and extensive viaducts, which was opened in the beginning of 1842; the Glasgow and Ayr Railway, about 40 miles long; the Glasgow, Paisley, and Greenock, 22½ miles long; the Dundee, Newtyle, and Cupar-Angus railways, about 17 miles long; the Dundee and Arbroath Railway, 17 miles in length; and the Arbroath and Forfar Railway, 15 miles long. Beside these, several others are projected, to connect Edinburgh and Newcastle, on the one hand, and with Dundee, Montrose, and Aberdeen, on the other. And we trust the period is not far distant, when every part of our country shall be intersected with these cheap and expeditious modes of conveyance.—The most prosperous of all the lines is that of the London and Birmingham, the *weekly* revenue of which is upward of £16,000; the weekly revenue of the Grand Junction, which joins it, is £900.—In the "Railway Magazine," July, 1842, the following calculation is given of a late weekly return of 40 railways, 1431 miles in length.—"Number of passengers on 25 railways, 289,819; consequently the total for the week, on the whole, must be about 400,000. The receipts for passengers on 39 railways, £74,938 15s. 6½d.; ditto for goods on 33 railways, £17,826 4s. 7½d.; total, £92,765 0s. 1½d. This is an average of £64 0s. ¾d. per mile, per week. The traffic, therefore, is at the rate of about four millions a year, and carrying fifteen millions of passengers."*

The velocity with which railway trains generally proceed, is from 20 to 25 miles per hour; but on some of the English railways it is much more rapid. The lines upon which the trains travel with the greatest speed are as follows:—Average speed exclusive of stoppages—*Northern and Eastern Railway* 36 miles per hour; *Great Western Railway* 33; *London and Brighton* 30; *Newcastle and North Shields* 30; *Midland Counties* 29; *Northland* 29; *London and Birmingham* 27;—At the ordinary rate of speed, a journey from London to Liverpool by the mail train—a distance of about 210 miles—is performed in about 9 hours; and when railways shall be extended from the South to Edinburgh, the journey from that city to London may be accomplished in less than 18 hours; so that a person may leave Edinburgh at 6 in the morning, and take supper in London the same evening—a journey which not long ago, occupied nearly a fortnight.

Traveling on railways is on the whole attended with less danger than in stage-coaches or any other mode of conveyance. The personal injuries and loss of life, which have occurred chiefly on the English railways, are, without almost an exception, to be attributed, either to the ignorance and carelessness of the engine drivers, or to the imprudence and recklessness of those who have been the victims of accidents. Were men of superior intelligence and prudence always employed to direct the motions of the trains, and were the public at large to attend to the restrictions and regulations prescribed in reference to railways, almost every accident might be prevented. On the Dundee and Arbroath Railway, which has been in operation for four years, scarcely an accident has ever occurred to any of the passengers, and those few which have happened on that line were entirely owing to the folly and imprudence of those who were the victims.

The *utility* of Railway communication, when properly conducted, must be obvious to all. In a commercial country, such as ours, the rapid conveyance of goods of all descriptions from one town to another, is an object of peculiar importance. Even in agricultural districts, the formation of railroads has enabled the landed proprietor to bring to a high state of cultivation extensive districts of land which would otherwise have remained barren and useless. But such advantages are as nothing, when compared with the increased diffusion of useful knowledge which must follow from a cheap and rapid conveyance over the British Empire, and over all those countries that have adopted similar modes of communication and transport.—Man is thus brought into juxta-position with his fellow-men; time and space are shortened, and cities a hundred miles distant may be considered as nearly adjacent, since they can be reached in the course of three or four hours. Friends, relatives, and correspondents can thus visit each other though at a distance, without much loss of time or money—communicate information, and interchange "brotherly kindness and affection." During the summer months, those confined in towns have an opportunity of taking excursions into the country for health and recreation, without any serious interference with the demands of business. Letters, newspapers, and periodicals of all descriptions, can be conveyed with a speed which, formerly, could neither have been effected nor anticipated. In certain cases, a letter may be written, sent through the Post-office, and delivered at the distance of 20 miles, in the course of a single hour. From Liverpool a letter may be dispatched to London, a distance of more than 200 miles, and an answer received in the course of the same day. As ignorance, superstition, and foolish prejudices, are the companions of those who live in retired districts, and seldom go beyond the view of the smoke of their father's chimney—so, when the great body of our fellow-men have an opportunity of taking extensive excursions through the country, we may expect that their minds will be expanded, their conceptions enlarged, and their views of nature and human society rendered more definite and extensive, so that they shall be enabled to take in ideas and portions of knowledge of which they were formerly ignorant. "Many shall run to and fro, and knowledge shall be increased." Beside, the frequent intercourse of man with his fellow-men of every grade has a natural tendency to promote friendship, esteem, and mutual affection. Civilization can alone be promoted by the frequent social intercourse of human beings; and wherever this intercourse exists, reciprocal benefits will always ensue; and such an intercourse among all ranks is now facilitated and promoted by the invention and formation of railways.

It is likewise obvious that Christianity and the Christian virtues may, by such improvements in traveling, be promoted and extended. "As in water face answereth to face, so doth the heart of man to man." In communicating religious instruction, admonition, and reproof, or in administering comfort under affliction, in most instances, the presence and countenance of a friend, and the living voice—breathing "words that burn," and which soothe or pierce the heart—generally produce a deeper and more permanent impression, where personal intercourse is obtained, than the same sentiments communicated by letter. "For as iron sharpeneth iron, so a man sharpeneth the countenance of his friend." We can also conceive many cases in which the labors of a minister of religion, and of a Christian missionary, may be greatly facilitated and rendered successful by a rapid conveyance from one place to another, and where missionary and other philanthropic associations would be more numerously attended and patronized by Christians having a cheap and expeditious conveyance to the places in which they are held. In short, were such modes of traveling introduced into every country, we should quickly hear of what is passing in all parts of the world, and learn the aspect of the Divine dispensations toward all nations; we should learn, without loss of time, the result of all the missionary enterprises which have been undertaken for the conversion and renovation of the heathen world, and be in readiness to send forth, by a speedy course, other missionaries wherever they were wanted, to spread abroad the fame of the Redeemer, and the knowledge of that Revelation which points out the way to a blessed immortality.

---

* The number of passengers booked for Edinburgh, at the several stations, on the Edinburgh and Glasgow Railway, on the 9th of August, 1842—the day of the Highland Society's exhibition—amounted to 4883.

In the preceding sketches I have presented a few specimens of the relation which the inventions of human ingenuity bear to religious objects. I intended to have traced the same relation in several other instances: in the invention of the electrical machine, the air-pump, mills, clocks, and watches, gas-lights, chemical fumigations, inventions for enabling us to walk upon the water, to prevent and alleviate the dangers of shipwreck, etc. But as my prescribed limits will not permit further enlargement, I trust that what has been already stated will be sufficient to establish and illustrate my general position. From this subject we may learn:—

1. That the various processes of art, and the exertions of human ingenuity, are under the special direction of Him who arranges all things "according to the counsel of his will." As "the king's heart is in the hand of the Lord, and as the rivers of waters he turns it whithersoever he pleases," so all the varied schemes and movements of the human mind, the discoveries of science, and the diversified experiments of mechanics, chemists, and philosophers, are directed in such channels as may issue in the accomplishment of His eternal purposes, in respect to the present and future condition of the inhabitants of our world. This truth is also plainly taught us in the records of Inspiration. "Doth the plowman plow all day to sow? Doth he open and break the clods of his ground? When he hath made plain the face thereof, doth he not cast abroad the vetches, and scatter the cummin,* and cast in the wheat in the principal [place], and the barley in the appointed place, and the rye in its proper place? *For his God doth instruct him to discretion, and doth teach him.* This also cometh forth from the Lord of hosts, who is wonderful in counsel, and excellent in working." Agriculture has, by most nations, been attributed to the suggestions of Deity; for "every good and perfect gift cometh down from the Father of lights." It is he who hath taught men to dig from the bowels of the earth, iron, copper, lead, silver, and gold, and to apply them to useful purposes in social life, and who hath given them "wisdom and understanding" to apply the animal and vegetable productions of nature to the manufacture of cloths, linen, muslin, and silk, for the use and the ornament of man. For "all things are of God." "Both riches and honor come from him, and he reigneth over all, and in his hand is power and might, and in his hand it is to make great, and to give strength to all." When the frame of the Mosaic Tabernacle and all its curious vessels were to be constructed, the mind of Bezaleel "was filled with the Spirit of God, in wisdom and understanding, and in knowledge, and in all manner of workmanship, to devise curious works in gold, and in silver, and in brass." And when the fabric of the New Testament Church is to be reared, and its boundaries extended, artificers of every description, adequate for carrying on the different parts of the work, are raised up, and inspired with the spirit of their respective departments—some with the spirit of writing, printing, and publishing; some with the spirit of preaching, lecturing, and catechising; some with the spirit of fortitude, to make bold and daring adventures into distant barbarous climes; and others with the spirit of literature, of science, and of the mechanical arts—all acting as pioneers "to prepare the way of the Lord," and as builders for carrying forward and completing the fabric of the Christian Church.

2. All the mechanical contrivances to which I have adverted, all the discoveries of science, and all the useful inventions of genius which may hereafter be exhibited, ought to be viewed as preparing the way for the *millennial era* of the church, and as having a certain tendency to the melioration of the external condition of mankind during its continuance. We are certain, from the very nature of things, as well as from scriptural prediction, that, when this period advances toward the summit of its glory, the external circumstances of this world's population will be comfortable, prosperous, and greatly meliorated, beyond what they have ever been in the days that are past—"Then shall the earth yield her increase, and God, even our own God, shall bless us." "Then shall he give the rain of thy seed, that thou shalt sow the ground withal; and bread of the increase of the earth, and it shall be fat and plenteous: in that day shall thy cattle feed in large pastures. The oxen likewise, and the young asses that ear the ground, shall eat savory provender, which hath been winnowed with a shovel and with the fan." "And the inhabitant shall not say, I am sick." "They shall build houses and inhabit them; and they shall plant vineyards, and eat the fruit of them. They shall not build, and another inhabit; they shall not plant, and another eat: for *as the days of a tree are the days of my people*, and mine elect shall *long enjoy* the work of their hands. They shall not labor in vain, nor bring forth for trouble; for they are the seed of the blessed of the Lord, and their offspring with them." "The seed shall be prosperous; the vine shall give her fruit, and the ground shall give her increase, and the heavens shall give their dew." "The evil beasts shall cease out of the land: and they shall sit every man under his vine, and under his fig-tree; and none shall make him afraid." "For wars shall cease to the ends of the world; and the knowledge of the Lord shall cover the earth, as the waters cover the sea." * Diseases will be, in a great measure, banished from the world, and the life of man extended far beyond its present duration—agriculture will be brought to perfection—commodious habitations erected for the comfortable accommodation of all ranks—cities built on elegant and spacious plans, adapted to health, ornament and pleasure; divested of all the filth, and darkness and gloom, and narrow lanes, which now disgrace the abodes of men—roads will be constructed on improved principles, with comfortable means of retreat for shelter and accommodation at all seasons; and conveyances invented for the ease, and safety, and rapid conveyance of persons and property from one

---

* *Vetches* is a kind of seed frequently sown in Judea, for the use of cattle; and *cummin* is the seed of a plant somewhat like fennel.

* Psalm lxvii. 6; Isaiah. xxx. 23, 24: xxxiii. 24; lxv. 21-23; Zech., viii. 12; Micah, iv. 4, etc.

place to another. Either the climates of the earth will be meliorated by the universal cultivation of the soil, so that storms and tempests, thunders and lightnings, shall no longer produce their present ravages; or chemical and mechanical contrivances will be invented to ward off their destructive effects. The landscape of the earth will be adorned with vegetable and architectural beauty; and, instead of horse-racing, demoralizing plays, routs and masquerades, boxing and bull-fights—artificial displays of scenery will be exhibited, more congenial to the dignity of rational, renovated, and immortal minds. For "the knowledge of the Lord," and the "beauties of holiness," will pervade men of all ranks and ages, "from the least even to the greatest."*

Now, as we have no reason to expect any *miraculous interference*, we must regard the past and the future useful inventions of philosophy and mechanics, as having a bearing on this glorious period, and a tendency to promote the improvement and the felicity of those who shall live during this era of Messiah's reign. If diseases are to be generally abolished, it will be owing to the researches of the scientific physician in discovering certain antidotes against every disorder, and to the practice of temperance, meekness, equanimity, and every other mean of preserving the vigor of the animal frame. For vicious passions and pursuits are the source of numerous disorders which, along with the anxieties, perplexities, and remorse which accompany them, gradually prey upon the human frame, and cut short the period of human existence—while the regular exercise of faith, love, hope, joy, and other Christian graces have an evident tendency to promote both health and longevity. If the earth is to produce its treasures in abundance, and with little labor, it will be owing in part to the improvement of agricultural science, and of the instruments by which its operations are conducted. If the lightnings of heaven shall no longer prove destructive to man and to the labors of his hands, it will be effected either by machinery for drawing off the electricity of a stormy cloud, or by the invention of *thunder-guards*, which shall afford a complete protection from its ravages. In these, and numerous other instances, the inventions of men, under the guidance of the Spirit of Wisdom, will have a tendency to remove a great part of the *curse* which has so long hung over our sinful world. And since the inventions of human skill and ingenuity for the melioration of mankind, and for the swift conveyance of intelligence, have of late years been rapidly increasing, *at the same time* when the Christian world is roused to increased exertions in disseminating the Scriptures throughout all lands, when general knowledge is increasingly diffused, and when the fabric of Superstition and Despotism is shaking to its foundations,—these combined and simultaneous movements seem plainly to indicate, that that auspicious era is fast hastening on, when "the glory of Jehovah shall be revealed, and all flesh shall see it together," when "righteousness and praise shall spring forth before all nations," and when "Holiness to the lord," shall be inscribed on all the pursuits, and implements, and employments of men.

Lastly, If the remarks suggested above be well-founded, we may conclude, that the mechanical and philosophical inventions of genius are worthy of the attentive consideration of the enlightened Christian, particularly in the relation they may have to the accomplishment of religious objects. He should contemplate the experiments of scientific men, not as a waste of time, or the mere gratification of an idle curiosity, but as embodying the germs of those improvements by which civilization, domestic comfort, knowledge, and moral principle, may be diffused among the nations. To view such objects with apathy and indifference, as beneath the regard of a religious character, argues a weak and limited understanding, and a contracted view of the grand operations of a superintending Providence.

CHAPTER IV.

SCRIPTURAL DOCTRINES AND FACTS ILLUSTRATED FROM THE SYSTEM OF NATURE.*

Without spending time in any introductory observations on this subject, it may be remarked in general,

I.—*That Scientific Knowledge, or an acquaintance with the System of Nature, may frequently serve as a guide to the true interpretation of Scripture.*

It may be laid down as a universal principle, that there can be no real discrepancy between a just interpretation of Scripture, and the facts of physical science; and on this principle the following canon is founded, which may be considered as an infallible rule for Scripture interpretation, namely,—*That no interpretation of Scripture ought to be admitted which is inconsistent with any well authenticated facts in the material world.* By *well*

---

* The various circumstances above stated, may be considered as the *natural results* of a state of society on which the light of science and of revelation has diffused its full influence, and where the active powers of the human mind are invariably directed by the pure principles and precepts of Christianity. That the duration of human life, at the era referred to, will be extended beyond its present boundary, appears to be intimated in some of the passages above quoted, particularly the following:—"*As the days of a tree shall be the days of my people,* and mine elect shall *long* enjoy the work of their hands." And if the life of man will be thus protracted to an indefinite period, it will follow, that those *diseases* which now prey upon the human frame, and cut short its vital action, will be in a great measure extirpated. Both these effects may be viewed (without supposing any miraculous interference) as the natural consequence of that happiness and equanimity which will flow from the practice of Christian virtues, from the enlargement of our knowledge of the principles of nature, and from the physical enjoyments which such a state of society will furnish.

* Under this head it was originally intended to embrace an elucidation of a considerable variety of the facts recorded in the Sacred History, and of the allusions of the inspired writers to the system of Nature; but as the volume has already swelled beyond the limits proposed, I am reluctantly compelled to confine myself to the illustration of only two or three topics

authenticated facts, I do not mean the theories of philosophers, or the deductions they may have drawn from them, nor the confident assertions or plausible reasonings of scientific men in support of any prevailing system of Natural science; but those facts which are universally admitted, and the reality of which every scientific inquirer has it in his power to ascertain; such as, that the earth is not an extended plane, but a round or globular body, and that the rays of the sun, when converged to a focus by a large convex glass, will set fire to combustible substances. Such facts, when ascertained, ought to be considered as a revelation from God, as well as the declarations of his word. For they make known to us a portion of his character, of his plans and of his operations.—This rule may be otherwise expressed as follows:—*Where a passage of Scripture is of doubtful meaning, or capable of different interpretations, that interpretation ought to be preferred which will best agree with the established discoveries of science.* For, since the Author of Revelation and the Author of universal nature is one and the same Infinite Being, there must exist a complete harmony between the revelations of his Word, and the facts or relations which are observed in the material universe. To suppose the contrary, would be to suppose the Almighty capable of inconsistency; a supposition which would go far to shake our confidence in the theology of Nature, as well as of Revelation. If, in any one instance, a Record claiming to be a revelation from heaven, were found to contradict a well known fact in the material world; if, for example, it asserted in express terms, to be literally understood, that the earth is a *quiescent* body in the center of the universe, or that the moon is no larger than a mountain—it would be a fair conclusion, either that the revelation is not Divine—or that the passages embodying such assertions are interpolations—or that science, in reference to these points, has not yet arrived at the truth. The example, we are aware, is inapplicable to the Christian revelation, which rests securely on its own basis, and to which science is gradually approximating, as it advances in the amplitude of its views, and the correctness of its deductions; but it shows us how necessary it is, in interpreting the *Word* of God, to keep our eye fixed upon his *Works;* for we may rest assured, that *truth* in the one will always correspond with *fact* in the other.

To illustrate the rule now laid down, an example or two may be stated.—If it be a fact, that geological research has ascertained that the materials of the strata of the earth are of a more ancient date than the Mosaic account of the commencement of the present race of men—the passages in the first chapter of Genesis, and other parts of Scripture, which refer to the origin of our world, must be explained as conveying the idea, that the earth was then merely *arranged* into its present form and order, out of the materials which *previously existed*, and which had been created by the Almighty at a period prior in duration. For Moses nowhere asserts that the materials of our globe were created or brought into existence out of nothing, at the time to which his history refers; but insinuates the contrary. "For the earth," says he, prior to its present constitution, "*was* without form and void," etc.—Again, if it be a fact that the universe is indefinitely extended, that, of many millions of vast globes which diversify the voids of space, only two or three have any immediate connection with the earth—then it will appear most reasonable to conclude, that those expressions in the Mosaic history of the creation, which refer to the creation of the fixed stars, are not to be understood as referring to the *time* when they were brought into existence, as if they had been created about the same time with our earth; but as simply declaring the fact, that, at what period soever in duration they were created, *they derived their existence from God.* That they did not all commence their existence at that period, is demonstrable from the fact, that, within the space of 2000 years past, and even within the space of the last two centuries, new stars have appeared in the heavens, which previously did not exist in the concave of the firmament; which, consequently, have been created since the Mosaic period; or, at least, had undergone a change analogous to that which took place in our globe, when it emerged from a chaotic state, to the form and order in which we now behold it. Consequently, the phrase, "God rested from all his works," must be understood, not absolutely, or in reference to the whole system of nature, but merely in relation to our world; and as importing, that the Creator then ceased to form any new species of beings *on the terraqueous globe.*—The same canon will direct us in the interpretation of those passages which refer to the last judgment, and the destruction of the present constitution of our globe. When, in reference to these events, it is said, that "the stars shall fall from heaven," that "the powers of heaven shall be shaken," and that "the earth and the heaven shall flee away," our knowledge of the system of nature leads us to conclude, either that such expressions are merely metaphorical, or that they describe only the *appearance*, not the *reality* of things. For it is impossible that the stars can ever fall to the earth, since each of them is of a size vastly superior to our globe, and could never be attracted to its surface, without unhinging the laws and the fabric of universal nature. The *appearance*, however, of the "heaven fleeing away," would be produced, should the earth's diurnal rotation, at that period, be suddenly stopped, as will most probably happen; in which case, all nature, in this sublunary system, would be thrown into confusion, and the heavens, with all their host, would *appear* to flee away.

Now, the scientific student of Scripture alone can judiciously apply the canon to which I have adverted; he alone can appreciate its utility in the interpretation of the sacred oracles; for he knows the facts which the philosopher and the astronomer have ascertained to exist in the system of nature; from the want of which information many divines, whose comments on Scripture have, in other respects, been judicious, have displayed their ignorance, and fallen into egregious blunders, when attempting to explain the first chapters of Genesis, and several parts of the book of Job—which have tended to bring discredit on the oracles of heaven.

II.—*The System of Nature confirms and illustrates the Scriptural Doctrine of the* DEPRAVITY OF MAN.

In the preceding parts of this volume, I have stated several striking instances of Divine benevolence, which appear in the construction of the organs of the animal system, in the constitution of the earth, the waters, and the atmosphere, and in the *variety* of beauties and sublimities which adorn the face of nature; all which proclaim, in language which can scarcely be mistaken, that the Creator has a special regard to the happiness of his creatures. Yet the Scriptures uniformly declare, that man has fallen from his primeval state of innocence, and has violated the laws of his Maker; that "his heart is deceitful above all things, and desperately wicked;" and that "destruction and misery are in his ways." Observation and experience also demonstrate, that a moral disease pervades the whole human family, from the most savage to the most civilized tribes of mankind; which has displayed its virulence in those wars and devastations which have, in all ages, convulsed the world; and which daily displays itself in those acts of injustice, fraud, oppression, malice, tyranny, and cruelty, which are perpetrated in every country, and among all the ranks even of civilized life. That a world inhabited by moral agents of this description, would display, in its physical constitution, certain indications of its Creator's displeasure, is what we should naturally expect, from a consideration of those attributes of his nature with which we are acquainted. Accordingly we find, that, amidst all the evidences of benevolence which our globe exhibits, there are not wanting certain displays of "the wrath of Heaven against the ungodliness and unrighteousness of men," in order to arouse them to a sense of their guilt, and to inspire them with reverence and awe of that Being whom they have offended. The following facts, among many others, may be considered as corroborating this position.

In the first place, *The present state of the interior strata of the earth* may be considered as a presumptive evidence, that a moral revolution has taken place since man was placed upon the globe. When we penetrate into the interior recesses of the earth, we find its different strata bent in the most irregular forms; sometimes lying horizontally, sometimes projecting upward, and sometimes downward, and thrown into confusion; as if some dreadful concussion had spread its ravages through every part of the solid crust of our globe. This is visible in every region of the earth. Wherever the miner penetrates among his subterraneous recesses, wherever the fissures and caverns of the earth are explored, and wherever the mountains lay bare their rugged cliffs, the marks of ruin, convulsion, and disorder, meet the eye of the beholder. Evidences of these facts are to be found in the records of all intelligent travelers and geologists who have visited Alpine districts, or explored the subterraneous regions of the earth; of which I have already stated a few instances in the article *Geology*.—These facts seem evidently to indicate, that the earth is not now in the same state in which it originally proceeded from the hand of its Creator; for such a scene of disruption and derangement appears incompatible with that order, harmony, and beauty, which are apparent in the other departments of nature. We dare not assert, that such terrible convulsions took place by chance, or independent of the will of the Creator; nor dare we insinuate, that they were the effects of a random display of Almighty power; and, therefore, we are necessarily led to infer, that a *moral* cause connected with the conduct of the rational inhabitants of the globe, must have existed, to warrant so awful an interposition of Divine Power; for the fate of the animated beings which then peopled the earth, was involved in the consequences which must have attended this terrible catastrophe. The volume of Revelation on this point, concurs with the deductions of reason, and assigns a cause adequate to warrant the production of such an extraordinary effect. "The wickedness of man was GREAT upon the earth; the earth was FILLED WITH VIOLENCE; every purpose and desire of man's heart was ONLY EVIL CONTINUALLY." Man had frustrated the end of his existence; the earth was turned into a habitation of demons; the long period to which his life was protracted, only served to harden him in his wickedness, and to enable him to carry his diabolical schemes to their utmost extent, until the social state of the human race became a scene of unmixed depravity and misery. And the physical effects of the punishment of this universal defection from God, are presented to our view in every land, and will remain to all ages, as a visible memorial that man has rebelled against the authority of his Maker.*

2. *The existence of volcanoes and the terrible ravages they produce*, bear testimony to the state of man as a depraved intelligence. A volcano is a mountain generally of an immense size, from whose summit issue fire, smoke, sulphur, and torrents of melted lava.† Previous to an eruption, the smoke, which is continually ascending from the *crater*, or opening in the top, increases and shoots up to an immense hight; forked lightning issues from the ascending column; showers of ashes are thrown out to the distance of forty or fifty miles; volleys of red-hot stones are discharged to a great hight in the air; the sky appears thick and dark; the luminaries of heaven disappear; and these terrible forebodings are accompanied with thunder, lightning, frequent concussions of the earth, and dreadful subterraneous bellowings. When these alarming appearances have continued sometimes four or five months, the lava begins to make its appearance, either boiling over the top, or forcing its way through the side of the mountain. This fiery deluge of melted minerals rolls down the declivity of the mountain, forming a dismal flaming stream, sometimes fourteen miles long, six miles broad, and 200 feet deep. In its course it destroys orchards, vineyards, corn-fields, and villages; and sometimes cities, containing twenty thousand inhabitants, have been swallowed up and consumed. Several other phenomena, of awful sublimity, sometimes accompany these eruptions. In the eruption of Vesuvius, in 1794, a shock of an earthquake was felt; and, at the same instant, a fountain of bright fire, attended with the blackest smoke and a loud report, was seen to issue, and to rise to a great hight from the cone of the mountain; and was soon succeeded by fifteen other fiery fountains, all in a direct line, extending for a mile and a half downward. This fiery scene was accompanied with the loudest thunder, the incessant reports of which, like those of a numerous heavy artillery, were attended by a continued hollow murmur, similar to that of the roaring of the ocean during a violent storm. The houses in Naples, at seven miles distance, were for several hours in a constant tremor; the bells ringing, and doors and windows incessantly rattling and shaking. The murmur of the prayers and lamentations of a numerous population added to the hor-

---

* It is not meant here to insinuate that *all* the dislocations and irregularities found in the strata of the earth are to be attributed to the action of the deluge; but it can scarcely be called in question, that certain traces of the effects of this catastrophe are to be found in most countries. The simple fact recorded in Revelation, that "the fountains of the great deep were broken up, and the flood-gates of the heavens opened"—that "the storm of rain continued upon the earth forty days and forty nights," and that the earth was covered with water for nearly the space of a whole year—could not but produce a very sensible and extensive effect upon the solid parts of the globe, though it may be difficult in some instances to distinguish some of the effects produced by Noah's flood from those which were the result of previous catastrophes. At any rate, the sacred historian is explicit in declaring it was "because the wickedness of man was great," that "a flood of waters was brought upon the earth."

† See page 58

rors of the scene. All travelers who have witnessed these eruptions seem to be at a loss to find words sufficiently emphatic to express the terrors of the scene. "One cannot form a juster idea," says Bishop Berkley, "of the *noise* emitted by the mountain, than by imagining a mixed sound made up of the raging of a tempest, the murmur of a troubled sea, and the roaring of thunder and artillery, confused altogether. Though we heard this at the distance of twelve miles, yet it was *very terrible*." In 1744, the flames of Cotopaxi, in South America, rose 3000 feet above the brink of the crater, and its roarings were heard at the distance of *six hundred miles*. "At the port of Guayaquil, 150 miles distant from the crater," says Humboldt, "we heard day and night the noise of this volcano, like continued discharges of a battery, and we distinguished these tremendous sounds even on the Pacific ocean."

The most terrific and extraordinary volcano yet known is that of Kirauea, lately discovered in Hawaii, one of the Sandwich islands. When the crater of this volcano first bursts upon the sight, there is an appearance presented of an immense plain below, 15 or 16 miles in circumference, and from 200 to 400 feet below its original level, covered with hillocks of lava, and vast floods of burning matter in a state of terrific ebullition, moving to and fro its fiery surge and flaming billows. Mr. Ellis, who beheld this volcano, states that, around the edge, or from the surface of the burning lake, there arose no fewer than 51 conical islands of varied form and size, containing as many craters. Twenty-two were constantly emitting columns of gray smoke or pyramids of brilliant flame, and several of these at the same time vomited from their ignited mouths streams of lava which rolled in blazing torrents down their black indented sides into the boiling mass below. The roar and noise emitted from these several craters resemble the sounds of a mighty steam-engine—*a whole lake of fire* appearing in the distance—billow after billow tossing its monstrous bosom in the air, and throwing forth its fiery spray to the hight of 40 or 50 feet—forming a scene most awfully grand and terrific—flames bursting forth from the largest cone, red-hot stones, cinders, and ashes propelled to a mighty hight with immense violence, and appalling floods of lava boiling down the sides over the surrounding scoriæ. Mr. Stewart and a party from the Blonde frigate visited this volcano in 1825. The following is only a very small part of his description:—"At night, splendid illuminations were lighted up; the volcano began roaring and laboring with redoubled activity. The confusion of noises was prodigiously great—rolling from one end of the crater to the other, sometimes seeming to be immediately under us, when a sensible tremor of the ground took place, and then again rushing to the farther end with incalculable velocity. The whole air was filled with the tumult, and soon after flames burst from a large cone near which we had been in the morning. Red-hot stones, cinders, and ashes were also propelled to a great hight with immense violence, and shortly after the molten lava came boiling up and flowed down the sides of the cone and over the surrounding scoriæ, in two beautiful streams, glittering with indescribable brilliance. At the same time, a whole lake of fire opened in a more distant part; this could not have been less than *two miles* in circumference; and its action was more horribly sublime than anything I ever imagined to exist, even in the ideal visions of unearthly things." This fiery volcano of Kirauea, the largest of which we have any record, dwindles into insignificance, when we think of the probable subterranean fires immediately beneath the whole of these and other South-Sea islands. The whole of Hawaii (Owhyhee), covering a space of 4000 square miles, is a complete mass of lava or other volcanic matter in various stages of decomposition. Perforated with innumerable apertures in the shape of craters, it forms a hollow cone over one vast furnace, situated in the heart of a stupendous submarine mountain rising from the bottom of the sea. When we contemplate such awful and overwhelming phenomena, the workmanship of Him who laid the foundations of the earth, and who superintends the operation of all its elementary principles, we have reason to exclaim, "Let the nations say unto God, how terrible art thou in thy works! Let all the earth fear Jehovah; let all the inhabitants of the world stand in awe of him!"

The *ravages* produced by volcanoes are in proportion to the terror they inspire. In the eruption of Etna in 1669, the stream of lava destroyed, in forty days, the habitations of 27,000 persons; and, of 20,000 inhabitants of the city of Catania, only 3000 escaped. In the year 79, the celebrated cities of Pompeii and Herculaneum were completely overwhelmed and buried under ground by an eruption of Vesuvius, and the spots on which they stood remained unknown for 1600 years. Since that period, about forty eruptions have taken place, each of them producing the most dreadful ravages. But the volcanoes of Asia and America are still more terrible and destructive than those of Europe. The volcanic mountain Pichincha, near Quito, caused, on one occasion, the destruction of 35,000 inhabitants. In the year 1772, an eruption of a mountain in the island of Java destroyed forty villages, and several thousands of the inhabitants; and in October, 1822, eighty-eight hamlets and above 2000 persons were destroyed in the same island, by a sudden eruption from a new volcano. The eruption from Tomboro, in the island of Sumbawa, in 1815, was so dreadful that all the Moluccas, Java, Sumatra, and Borneo, to the distance of a thousand miles from the mountain, felt tremulous emotions, and heard the report of explosions. In Java, at the distance of 340 miles, the clouds of ashes from the volcano produced utter darkness.

Volcanoes are more numerous than is generally imagined. They are to be found in every quarter of the world, from the icy shores of Kamtschatka to the mountains of Patagonia. Humboldt enumerates forty volcanoes constantly burning between Cotopaxi and the Pacific ocean; twenty have been observed in the chain of mountains that stretches along Kamtschatka; and many of them are to be seen in the Philippines, the Moluccas, the Cape de Verd, the Sandwich, the Ladrone, and other islands in the Indian and Pacific oceans. It is stated in vol. 6th of *Supp. to Encyc. Brit.*, that about 205 volcanoes are known, including only those which have been active within a period to which history or tradition reaches. Europe contains 14; and, of the whole number, it is computed that 107 are in islands, and 98 on the great continents.

Can we then suppose that so many engines of terror and destruction, dispersed over every quarter of the globe, are consistent with the conduct of a benevolent Creator toward an *innocent* race of men? If so, we must either admit that the Creator had it not in his power, when arranging our terrestrial system, to prevent the occasional action of these dreadful ravages; or, that he is indifferent to the happiness of his innocent offspring. The former admission is inconsistent with the idea of his Omnipotence, and the latter with the idea of his universal Benevolence. It is not, therefore, enthusiasm, but the fairest deduction of reason to conclude, that they are indications of God's displeasure against a race of transgressors who have apostatized from his laws.

3. The same reasoning will apply to the ravages produced by *Earthquakes*. Next to volcanoes, earthquakes are the most terrific phenomena of nature, and are even far more destructive to man, and to the labors of his hands. An earthquake, which consists in a sudden motion of the earth, is generally preceded by a rumbling sound, sometimes like that of a number of carriages driving furiously along the pavement of a street, sometimes like the rushing noise of a mighty wind, and sometimes like the explosions of artillery. Their effect on the surface of the earth is various. Sometimes it is instantaneously heaved up in a perpendicular direction, and sometimes it assumes a kind of rolling motion, from side to side.—The ravages which earthquakes have produced are terrible beyond description; and are accomplished almost in a moment. In 1692, the city of Port-Royal, in Jamaica, was destroyed by an earthquake, in the space of two minutes, and the houses sunk into a gulf forty fathoms deep. In 1693, an earthquake happened in Sicily, which either destroyed or greatly damaged fifty-four cities and an incredible number of villages. The city of Catania was utterly overthrown; the sea all of a sudden began to roar; Mount Etna to send forth immense spires of flame; and, immediately a shock ensued, as if all the artillery in the world had been discharged. The birds flew about astonished; the sun was darkened; the beasts ran howling from the hills; a dark cloud of dust covered the air; and though the shock did not last three minutes, yet nineteen thousand of the inhabitants of the city perished in the ruins. This shock extended to a circumference of 7000 miles.

Earthquakes have been producing their ravages in various parts of the world, and in every age, and are still continuing their destructive effects. Pliny informs us, that twelve cities in Asia Minor were swallowed up in one night. In the year 115, the city of Antioch, and a great part of the adjacent country, were buried by an earthquake. About 300 years after, it was again destroyed along with 40,000 inhabitants; and, after an interval of only 60 years, it was a third time overturned, with the loss of not less than 60,000 souls. In 1755, Lisbon was destroyed by an earthquake, and it buried under its ruins above 50,000 inhabitants. The effects of this terrible earthquake were felt over the greater part of Europe and Africa, and even in the midst of the Atlantic ocean; and are calculated to have extended over a space of not less than four millions of square miles. In August, 1822, two-thirds of the city of Aleppo, which contained 40,000 houses, and 200,000 inhabitants, were destroyed by an earthquake, and nearly 30,000 inhabitants were buried under the ruins.—On the 7th May, 1842, at 5 o'clock in the evening, the town of Cape Haytien, in the island of St. Domingo, was totally destroyed by an earthquake, and ten thousand of the inhabitants—forming two-thirds of the population—perished in the catastrophe. The towns of St. Nicholas and Port Paix, were also tumbled into ruins, and most if not all towns on the north side of the island, in some of which multitudes of the inhabitants were destroyed, amounting in all to about 20,000 human beings, who perished in that tremendous concussion. Its effects were traced from W. Longitude 56° in the northern part of the tropics, to W. Longitude 91°, comprehending an extent, from east to west, of 35°, passing along Cuba, Louisiana, and part of the United States.

To suppose that the human beings who have been victims to the ravages of earthquakes and volcanoes, "were sinners above all those who dwelt around them," would be the hight of impiety and presumption. But the fact, that thousands of rational beings have been swept from existence, in a manner so horrible and tremendous, seems plainly to indicate, that they belonged to a race of apostate intelligences, who had violated the commands of their Creator. Such visitations are quite accordant to the idea of man being in the condition of a transgressor; but, if he were an *innocent* creature, they would be altogether unaccountable, as happening under the government of a Being of unbounded benevolence.

4. The phenomena of *thunder-storms*, *tempests*, and *hurricanes*, and the ravages they produce, are also presumptive proofs that man is a depraved intelligence. In that season of the year when Nature is arrayed in her most beautiful attire, and the whole terrestrial landscape tends to inspire the mind with cheerfulness—suddenly a sable cloud emerges from the horizon—the sky assumes a baleful aspect—a dismal gloom envelops the face of Nature—the lightnings flash from one end of the horizon to another—the thunders roll with awful majesty along the verge of heaven, until at length they burst over head in tremendous explosions. The sturdy oak is shattered and despoiled of its foliage; rocks are rent into shivers; and the grazing herds are struck into a lifeless group. Even *man* is not exempted from danger in the midst of this appalling scene. For hundreds in every age have fallen victims either to the direct stroke of the lightning, or to the concussions and conflagrations with which it has been attended. In tropical countries, the phenomena of thunder-storms are more dreadful and appalling than in our temperate climate. The thunder frequently continues for days and weeks in almost one incessant roar; the rains are poured down in torrents; and the flashes of lightning follow each other in so rapid a succession, that the whole atmosphere and the surrounding hills seem to be in a blaze. In some instances, the most dreadful effects have been produced by the bursting of an electrical cloud. In 1772, a bright cloud was observed at midnight to cover a mountain in the island of Java; it emitted globes of fire so luminous that the night became as clear as day. Its effects were astonishing. Everything was destroyed for seven leagues around; houses were demolished; plantations buried in the earth; and 2140 people lost their lives, beside 1500 head of cattle, and a vast number of horses and other animals.*

Is it not reasonable, then, to conclude, that such awful phenomena as storms, volcanoes, and earthquakes are so many occasional indications of the frown of an offended Creator upon a race of transgressors, in order to arouse them to a sense of their apostasy from the God of heaven? We cannot conceive that such physical operations, accompanied by so many terrific and destructive effects, are at all compatible with the idea, that man is at present in a *paradisiacal* state, and possessed of that *moral* purity in which he was created Such appalling displays of Almighty power are in complete unison with the idea, that man is a transgressor, and that the present dispensations of God are a mixture of mercy and of judgment; but if he belong to an innocent race of moral intelligences, they appear quite anomalous, and are altogether inexplicable, on the supposition, that a Being of infinite benevolence and rectitude directs the operations of the physical and moral world; more especially when we consider the admirable care which is displayed in the construction of animal bodies, in order to prevent pain, and to produce pleasurable sensations. When man was first brought into existence, his thoughts and affections, we must suppose, were in unison with the will of his Creator; his mind was serene and unruffled; and, consequently, no foreboding apprehensions of danger, would, in such a state, take possession of his breast. But after he had swerved from the path of primeval rectitude, and especially after the Deluge had swept away the inhabitants of the Antediluvian world, the constitution of the earth and the atmosphere seems to have undergone a mighty change, corresponding to the degraded state into which he had fallen; so that those very elements which may have formerly ministered to his enjoyment—by being formed into different combinations—now conspire to produce terror and destruction.

---

* Encyc. Brit., Art. *Cloud*

The same important conclusion might have been deduced, from a consideration of the immense deserts of marshes and barren sands which are dispersed over the globe—the vast and frightful regions of ice around the poles—the position of the mineral strata, and the vast disproportion which the extent of the dry land bears to the expanse of the ocean,—all which circumstances, and many others, in conjunction with the facts above stated, conspire to show, that man no longer stands in the rank of a pure intelligence; and that his habitation corresponds, in some degree, to his state of moral degradation. By overlooking this consideration, St. Pierre and other Naturalists have found themselves much at a loss, when attempting to vindicate the wisdom and equity of Providence, in the physical disorders which exist in the present constitution of our globe. The circumstance, that man is a fallen creature, appears the only clue to guide us in unraveling the mysteries of Providence, and to enable us to perceive the *harmony* and *consistency* of the Divine operations in the system of nature; and no other consideration will fully account for the disorders which exist in the present economy of our world.

But it is a most consoling consideration, that, amidst all the physical evils which abound, the benevolence and mercy of God are admirably blended with the indications of his displeasure.—Thunder-storms and tempests contribute to the purification of the atmosphere; and volcanoes are converted into funnels for vomiting up those fiery materials which produce earthquakes, and which might otherwise swallow up whole provinces in one mighty gulf. In the *ordinary course* of things, such phenomena are more terrific than destructive; and are calculated rather to rouse an unthinking world to consideration, than to prove the instruments of human destruction. Compared with the miseries which men have voluntarily inflicted on one another, the destructive effects of the elements of nature dwindle into mere temporary and trifling accidents. We have reason to believe, that a much greater destruction of human beings has been produced by two or three of the late battles in modern Europe, such as those of Waterloo, Borodino, and Smolensko, than has been produced by all the electrical storms, earthquakes, and volcanic eruptions, which have raged for the space of several hundred years. It has been calculated, that, during the Russian campaign of 1812, including men, women, and children, belonging to the French and Russians, there were not less than five hundred thousand human victims sacrificed to the demon of war. It is probable, that the destruction produced among the human race, by the convulsions of nature, since the commencement of time (the deluge only excepted), does not amount to above four or five millions of lives; but were we to take into account the destruction of human life produced by ambition, tyranny, oppression, superstition, wars, devastations, murders, and horrid cruelties, in every period of the world, it would, doubtless, amount to several thousands of millions. So that, amidst the most terrible displays of the displeasure of God against the sins of men, *mercy* is mingled with judgment; and while man is the greatest enemy and destroyer of his own species, benevolence is the *prominent* feature of all the arrangements of the Deity in the physical world. For although he is great in power he is slow to anger, and "his tender mercies are over all his works." The evils which flow from the operation of the elements of nature ought not to be considered as the inflictions of avenging justice, but as the kind admonitions of a benevolent Father, who willeth not that any should perish, but that all should come to repentance—and who has displayed his love to the human race in such a wonderful manner that "he gave his only-begotten Son, that whosoever believeth on him might not perish but have everlasting life."*

III.—*The Discoveries which have been made in the System of Nature illustrate the Doctrine of the* RESURRECTION OF THE DEAD.

The doctrine of a Resurrection from the dead, at first view, appears to involve in it a variety of difficulties and apparent contradictions. That a complex organical machine, as the human body is, consisting of thousands of diversified parts for the performance of its functions, after it has been reduced to atoms, and those atoms dispersed to "the four winds of heaven"—should be again reared up with the same materials, in a new and more glorious form,—is an idea which seems to baffle the human comprehension; and, in all probability, would never have entered the mind of man, had it not been communicated by Divine Revelation. Accordingly we find, that the philosophers of antiquity, though many of them believed in the doctrine of a future state, never once dreamed that the bodies of men, after they had been committed to the dust, would ever again be reanimated: and hence, when the Apostle Paul proposed this doctrine to the Athenian philosophers, they scouted the idea, as if it had been the revery of a madman. And, indeed, without a strong conviction, and a lively impression, of the infinite power and intelligence of God, the mind cannot rely with unshaken confidence on the declaration of a future fact so widely different from all the obvious phenomena of nature, and from everything that lies within the range of human experience. "If a man die," says Job, "shall he live again? There is hope of a tree, if it be cut down, that it will sprout again, and bring forth boughs like a plant. But man dieth and wasteth away; yea, man giveth up the ghost, and where is he?" When the mind, however, is frequently exercised in contemplations on the stupendous works of the Almighty, it must feel an impressive conviction, that "nothing can be too hard for Jehovah." When we endeavor to draw aside the vail which conceals many of the scenes of nature from the vulgar eye, we perceive a variety of operations and analogies, which tend to assist us in forming a conception, not only of the *possibility* of a resurrection, but also of the *manner* in which it may probably be effected, when the power of Omnipotence is interposed.

---

* The facts stated in this section are expressed, for the most part, in the author's own words, for the sake of compression.—His authorities are, Goldsmith's Natural History, Humboldt's Travels, Brydon's Tour, Sir W. Hamilton's Observations, Raffle's History of Java, Encyc. Brit., Arts. *Etna, Volcano, Earthquake, Antioch, Cloud*—Ellis's Polynesian Researches, etc.

The transformation of insects affords us a beautiful illustration of this subject. All the butterflies which we see fluttering about in the summer months were originally caterpillars. Before they arrive at that highest stage of their existence, they pass through four different transformations. The first state of a butterfly is that of an *egg;* it next assumes the form of a loathsome crawling *worm;* after remaining some time in this state, it throws off its caterpillar skin, languishes, refuses to eat, ceases to move, and is shut up, as it were, in a tomb. In this state, the animal is termed a *chrysalis:* it is covered with a thin crust or shell, and remains, sometimes for six or eight months, without motion, and apparently without life. After remaining its allotted time in this torpid condition, it begins to acquire new life and vigor; it bursts its imprisonment, and comes forth a butterfly, with wings tinged with the most beautiful colors. It mounts the air, it ranges from flower to flower, and seems to rejoice in its new and splendid existence. How very different does it appear in this state, from what it did in the preceding stages of its existence! How unlikely did it seem, that a rough, hairy, *crawling* worm, which lay for such a length of time, in a death-like torpor, and enshrouded in a tomb, should be reanimated, as it were, and changed into so beautiful a form, and indued with such powers of rapid motion! Perhaps the change to be effected on the bodies of men, at the general resurrection, may not be greater, nor more wonderful in its nature, than are the changes which take place from the first to the last stage of a caterpillar's existence.—In such transformations, then, we behold a lively representation of the death and resurrection of a righteous man. "A little while he shall lie in the ground, as the seed lies in the bosom of the earth; but he shall be raised again, and shall never die any more."

There is another illustration, taken from a consideration of the chemical changes of matter, which has a still more direct bearing on the doctrine of a resurrection. We know, that substances which are invisibly incorporated with air, water, and other fluids, and which seem to be destroyed, may be made to reappear in their original form by the application of certain chemical reagents. For example, put a small piece of solid camphor into a vial half filled with alcohol or spirit of wine—in a short time the camphor will be dissolved in the fluid, and the spirit will be as transparent as at first. If water be now added, it will unite with the ardent spirit, and the camphor will be separated and fall to the bottom of the vial. In this way the camphor may be nearly all recovered as at first; and, by distillation, the alcohol may also be separated from the water, and exhibited in a separate state. I have already noticed that *carbon,* which forms an essential part of all animal and vegetable substances, is found to be not only indestructible by age, but in all its combinations, which are infinitely diversified, it still preserves its *identity.* In the state of carbonic acid, it exists in union with earths and stones in unbounded quantities; and, though buried for thousands of years beneath immense rocks, or in the center of mountains, it is still carbonic acid: for no sooner is it disengaged from its dormitory, than it rises with all the life and vigor of recent formation, not in the least impaired by its torpid inactivity during the lapse of ages. The beams of the theater at Herculaneum were converted into *charcoal* (which is one of the compounds of carbon), by the lava which overflowed that city during an eruption of mount Vesuvius; and, during the lapse of 1700 years, the charcoal has remained as entire as if it had been formed but yesterday, and it will probably continue so to the end of the world. In addition to these facts, it may be stated that provision has been made for the restoration of the fallen leaves of vegetables which rot upon the ground, and to a careless observer, would appear to be lost forever. It has been shown by experiment that, whenever the soil becomes charged with such matter, the oxygen of the atmosphere combines with it, and converts it into carbonic acid gas. The consequence of which is, that *this very same carbon* is, in process of time, absorbed by a new race of vegetables, which it clothes with a new foliage, and which is itself destined to undergo similar putrefaction and renovation to the end of time.*

These facts, and others of a similar description, which might have been stated, demonstrate, that one of the constituent parts of animal bodies remains unalterably the same amidst all the revolutions of time, and all the changes and decompositions which take place in the system of nature; and, consequently that though human bodies may remain in a state of putrefaction for ages, in the earth and in the waters, yet their component parts remain unchanged, and in readiness to enter into a new and more glorious combination, at the command of that INTELLIGENCE, to whom all the principles of nature, and all their diversified changes, are intimately known; and whose POWER is able to direct their combinations to the accomplishment of his purposes.—Though such considerations as these may have no weight on certain unreflecting minds, that never met with any difficulties in the economy either of Nature or of Redemption—yet the man of deep reflection, who has frequently had his mind distracted with the apparent improbability of the accomplishment of certain divine declarations, will joyfully embrace such facts in the economy of nature, as a *sensible support* to his faith in the promises of his God; and will resign his body to dust and putrefaction, in the firm hope of emerging from the tomb to a future and more glorious transformation.

IV.—*The Discoveries of Science tend to illustrate the Doctrine of the* GENERAL CONFLAGRATION.

We are informed, in the Sacred Oracles, that a period is approaching, when "the elements shall melt with fervent heat, and the earth, and the works that are therein, shall be burned up." Science has ascertained certain facts in the constitution of nature, which lead us to form some conception of the *manner* in which this awful catastrophe may probably be effected, and also of the ease with which it may be accomplished, when the destined period shall have arrived. It was formerly stated (pp. 32, 105), that the atmosphere, or the air we breathe, is a compound substance, composed of two very different and opposite principles, termed *oxygen* and *nitrogen*. The oxygen, which forms about a fifth part of the atmosphere, is now ascertained to be the principle of flame: a lighted taper, immersed in this gas, burns with a brilliancy too great for the eye to bear; and even a rod of iron or steel is made to blaze under its energy.

---

* Parke's Chemical Cathecism, p. 266, and the additional Notes.

The modern infidel, like the scoffers of old, scouts the idea of the dissolution of the world, and of the restitution of the universe, because all things continue as they were from the beginning of the creation; not knowing the Scriptures, nor the Power of God; and not considering the principles and facts in the system of nature, which indicate the possibility of such an event. But, from the fact now stated, we may learn, how easily this effect may be accomplished, even in conformity with those laws which now operate in the constitution of our globe. For, should the Creator issue forth his Almighty fiat—"Let the nitrogen of the atmosphere be completely separated from the oxygen, and let the oxygen exert its native energies without control, wherever it extends;"—from what we know of its nature, we are warranted to conclude, that instantly a universal conflagration would commence throughout all the kingdoms of nature—not only wood, coals, sulphur, bitumen, and other combustible substances, but even the hardest rocks and stones, and all the metals, fossils, and minerals, and water itself, which is a compound of two inflammable substances, would blaze with a rapidity which would carry destruction through the whole expanse of the terraqueous globe, and change its present aspect into that of a new world:—at the same time, all the other laws of nature might still operate as they have hitherto done since the creation of the world.

I do not mean positively to assert, that this is the agent which the Almighty will certainly employ for accomplishing this terrible catastrophe (though I think it highly probable), since Infinite Power is possessed of numerous resources for accomplishing its objects, which lie beyond the sphere of our knowledge and comprehension. But I have brought forward this fact, to show with what infinite ease this event may be accomplished, when Almighty Power is interposed. By means of the knowledge we have acquired of the constitution of the atmosphere, and by the aid of chemical apparatus, we can perform experiments on a *small scale*, similar in kind, though infinitely inferior in degree, to the awful event under consideration. And, therefore, we can easily conceive that He who formed the expansive atmosphere which surrounds us, and who knows the native energy of its constituent principles, may, by a simple volition, make that invisible fluid, in a few moments, the cause of the destruction of the present constitution of our world, and, at the same time, the means of this subsequent renovation. For, as fire does not annihilate, but only changes the forms of matter, this globe on which we now tread, and which bears the marks of ruin and disrupture in several parts of its structure, may come forth from the flames of a general conflagration, purified from all its physical evils, adorned with new beauties and sublimities, and rendered a fit habitation for pure intelligences, either of our own species or of another order. For though "the heavens," or the atmosphere, "shall be dissolved, and the elements melt with fervent heat;" "yet," says the apostle Peter, "we, according to his promise, look for new heavens and a new earth, wherein dwelleth righteousness." Whether, after being thus renovated, it shall be allotted as the residence of the redeemed inhabitants of our world, is beyond our province at present to determine. But if not, it will, in all probability, be allotted as the abode of other rational beings, who may be transported from other regions, to contemplate a new province of the Divine empire, or who may be immediately created for the purpose of taking possession of this renovated world. For we have reason to believe that the energies of Creating Power will be continually exerted, in replenishing the boundless universe, throughout all the ages of infinite duration; and that no substances, or worlds, which God has created, will ever be suffered to fall into annihilation—at least, that the original atoms of matter will never be destroyed, whatever new forms they may assume, and however varied the combinations into which they may enter.

The above are only a few examples out of many which were intended to be specified, of the illustrations which the system of nature affords of the doctrines and facts of Revelation, but the narrow limits of this volume prevent further enlargement.

It was also intended to follow up the preceding discussions with particular illustrations of the following topics:—The views which science affords of the *incessant energies of Creating Power*—the changes and revolutions which appear to have happened, and which are still going on in the distant regions of the universe, *as tending to amplify our views of the grand and multifarious objects over which Divine Providence presides—the connection of science with a future state*—the aids which the discoveries of science afford, in enabling us to form a conception of the scenes of future felicity—of the employments of the heavenly inhabitants, and of their perpetual advances in knowledge and happiness, and in their views of the perfections of Deity*—the *moral relations of intelligent beings* to their Creator, and to each other; and the *physical grounds or reasons* of those moral laws which the Deity has promulgated, for regulating the conduct, and for promoting the harmony and order of intelligent agents†—illustrations of the allusions of the Sacred writers to the system of the material world—the *simultaneous progress of science and religion*, considered as an evidence of the connection of the one with the other—the *moral effects* of the study of science in connection with religion—replies to objections and insinuations which have been thrown out against the idea of combining the discoveries of Science with the discoveries of Revelation, &c. But, as illustrations of these, and various other topics connected with them, would occupy several hundreds of pages, they must, in the meantime, be postponed.‡

---

* Several of these subjects, along with many others, are fully illustrated in the author's volume, entitled, "The Philosophy of a Future State."

† These and a variety of kindred topics are illustrated at considerable length in my work entitled "*The Philosophy of Religion:* or, an illustration of the Moral Laws of the Universe, on the principles of reason and Divine Revelation"—in which an original and popular train of thought is prosecuted, and the different topics are enlivened with illustrative facts derived from the scenery of nature and the moral history of mankind.

‡ Several of the topics alluded to in this paragraph will be found more or less illustrated in the author's volumes, entitled "Celestial Scenery"—and "The Sidereal Heavens"—in which "the incessant energies of Creating Power"—the changes and revolutions which have happened and are still going forward in the distant regions of the universe—the doctrine of a plurality of worlds—and many other kindred topics, are particularly elucidated.

CHAPTER V.

BENEFICIAL EFFECTS WHICH MIGHT RESULT TO CHRISTIAN SOCIETY, FROM CONNECTING THE DISCOVERIES OF SCIENCE WITH THE OBJECTS OF RELIGION.

I.—*The* VARIETY OF TOPICS *which would be introduced into Christian Instructions, by connecting them with the manifestations of Deity in the system of Nature,* WOULD HAVE A TENDENCY TO ALLURE THE ATTENTION OF THE YOUNG TO RELIGIOUS SUBJECTS, *and to afford Mental Entertainment, and Moral Instruction, to intelligent minds of every description.*

NOVELTY and VARIETY appear to be essentially requisite in order to rouse the attention, not only of the more ignorant, but even of the more intelligent class of mankind, and to excite them to make progress in the path of intellectual and moral improvement. The principle of *curiosity,* which appears at a very early period of life, and which variegated scenery and novel objects tend to stimulate and to gratify—so far from being checked and decried, in a religious point of view, as some have been disposed to do, ought to be encouraged and cultivated in the minds both of the old and of the young. As it is a principle which God himself has implanted in our natures, for wise and important purposes, it requires only to be chastened, and directed in a proper channel, in order to become one of the most powerful auxiliaries in the cause of religion, and of intellectual improvement. To gratify this principle, and to increase its activity, the Creator has adorned our globe with a combination of beauties and sublimities, strewed in endless variety over all its different regions. The hills and dales, the mountains and plains; the seas, the lakes, the rivers; the islands of every form and size which diversify the surface of the ocean; the bays, the gulfs, and peninsulas; the forests, the groves, the deep dells, and towering cliffs; the infinite variety of trees, plants, flowers, and vegetable productions of every hue, so profusely scattered over the face of nature; the diversified productions of the mineral kingdom; the variegated coloring spread over the face of nature; together with the many thousands of different species of animated beings which traverse the air, the waters, and the earth—afford so many stimuli to rouse this principle into exercise, and to direct the mind to the contemplation of the Creator. And, as the earth displays an endless diversity of objects, so the heavens, in so far as they have been explored, exhibit a scenery both grand and variegated. There is not a planet in the Solar System but differs from another, in its magnitude, in its distance from the central luminary about which it revolves, in the velocity of its motion, in the extent of the circle it describes around the sun, in the period of time in which its revolution is completed, in its rotation round its own axis, in the number of moons with which it is attended, in the inclination of its axis to the plane of its orbit, and the diversity of seasons which results from this circumstance; in the density of its atmosphere, and the various appearances which diversify its surface. And, if we were favored with a nearer view of these majestic orbs, we should, doubtless, behold a similar variety in every part of their internal arrangements.—The surface of the moon presents a variegated prospect of mountains and vales, but so very different in their form, position, and arrangement, from what obtains on the surface of our globe, that it would exhibit a scenery altogether new and uncommon to an inhabitant of this world, were he placed on the surface of that planet. Every comet too is distinguished from another, by its magnitude, the extent of its atmosphere, the length of its blazing tail, the rapidity of its motion, and the figure of the curve it describes around the sun. With regard to the fixed stars, which are distributed, of every size, and in every direction, through the immensity of space, our senses as well as the declaration of an inspired writer, convince us, that in point of brilliancy, color, motion, and magnitude, "one star differeth from another star in glory." Almost every *Nebula* of the 3000 which have been discovered, differs from another in its figure, extent, brightness, and general appearance; and the motions of double and treble stars, as to the periods of their revolutions, are as diversified as those of the planets—some of them revolving around their centers in 30 or 40 years, others requiring 400, and even 1600 years to finish their circuits—some of them diffusing a bluish light, others a red, and others a brilliant white.

And as the system of nature in all its parts, presents a boundless variety of scenery, to arouse the attention, and to gratify the desire for novelty, so the revelation of God, contained in the Sacred Records, displays a diversified combination of the most sublime and interesting subjects and events. Were we to form an opinion of the compass of Divine Revelation, from the range of subjects to which the minds of some professing Christians are confined, it might all be comprehended within the limits of five or six chapters of the New Testament; and all the rest might be thrown aside, as a dead weight upon the Christian system. But here, as in all the other displays of the Almighty, Divine Perfection and Providence are exhibited in the most diversified aspects. Here we have recorded a history of the creation and arrangement of our globe—of the formation of the first human pair—of their primeval innocence, temptation, and fall—of the arts which were cultivated in the first ages of the world—of the increase of human wickedness—of the building of the ark—of the drowning of the world by a universal deluge—of the burning of Sodom by fire from the clouds—of the origin of languages—of the dividing of the Red sea—of the journeying of the tribes of Israel through the deserts of Arabia—of their conquest of the promised land, and their wars with the nations of Canaan—of the corporeal translation of

Elijah from earth to heaven—of the manifestation of the Son of God in human flesh, the benevolent miracles he performed, and the triumphs he obtained over all the powers of hell and earth.—We are here presented with the most interesting and affective narratives, elegies, dramatic poems, and triumphal songs,—with views of society in the earliest ages of the world, when the lives of men were prolonged to nearly a thousand years,—with splendid miracles performed in the land of Egypt, in the wilderness of Horeb, and in the "field of Zoan," when "the sun and moon stood still in their habitation;" when the waters of the great deep were divided, and mountains shook and trembled "at the presence of Jehovah,"—with the glorious marching of a whole nation through the Arabian deserts, under the guidance of a miraculous pillar of cloud and fire,—with the visits of celestial messengers, and the visible symbols of "a present Deity,"—with prophetical delineations of the present and future condition of the race of Adam, with descriptions of the Power, Wisdom, Love, and Majesty of the Almighty, and of his operations in Heaven and Earth,—with the results and bearings of the Economy of Redemption,—with Divine Songs, Odes, and Hymns, composed by angels and inspired men,—with maxims of moral wisdom, examples of sublime eloquence, of strength of reasoning, and of manly boldness of reproof—with Proverbs, Parables, Allegories, Exhortations, Promises, Threatenings, and Consolatory Addresses,—In short, we have here detailed, in the greatest variety—History, Antiquities, Voyages, Travels, Philosophy, Geography, Natural and Moral Science, Biography, Arts, Epic Poetry, Epistles, Memoirs, Delineations of Nature, Sketches of Human Character, Moral Precepts, Prophesies, Miracles, Narrations, Wonderful Providences, Marvelous Deliverances, the Phenomena of the Air, the Waters, and the Earth; the Past, the Present, and the Future Scenes of the World—all blended together in one harmonious system, without artificial order, but with a majesty and grandeur, corresponding to the style of all the other Works of God, and all calculated to gratify the principle of curiosity—to convey "reproof, correction, and instruction in righteousness," and "to make the man of God perfect, and thoroughly furnished to every good work."

And as the scenes of Nature, and the scenes of Revelation, are thus wonderfully diversified, in order to excite the attention of intelligent beings, and to gratify the desire for variety, so we have every reason to believe, that the scenes, objects, and dispensations which will be displayed in the heavenly world, will be incomparably more grand and diversified. When we consider the immensity of God's Universal Kingdom, and the numerous systems, and worlds, and beings comprehended within its vast circumference, and that the energies of Creating Power may be forever exerted in raising new worlds into existence—we may rest assured, that the desire of variety and of novelty in holy intelligences, will be completely gratified throughout an endless succession of existence; and that the most luxuriant imagination, in its boldest excursions, can never go beyond the reality of those scenes of diversified grandeur which the Heaven of heavens will display.

Now, since the Book of Nature and the Book of Revelation, since all the manifestations of the Creator in heaven and earth, are characterized by their sublime and diversified aspect—we would ask, why should we not be imitators of God, in displaying the diversified grandeur of his Kingdom of Providence and of Grace before the minds of those whom we profess to instruct? Why should we confine our views to a few points in the Christian system, to a few stones in the fabric of the Divine operations, when "a wide and unbounded prospect lies before us?" Why should we not rather attempt to rouse the moral and intellectual energies of mankind, from the pulpit, from the press, in the school-room, and in the family circle, by exhibiting the boundless variety of aspect which the Revelations of Heaven present, and the holy tendencies of devout contemplation on the Works and the Ways of God—that they may learn, with intelligence, to "meditate on *all* the works of the Lord, and to talk of *all* his doings?"—By enlarging and diversifying the topics of religious discussion, according to the views now stated, we have it in our power to spread out an intellectual feast to allure and to gratify every variety of taste,—the young and the old, the learned and the unlearned, yea, even the careless and the ignorant, the skeptical and the dissipated, might frequently be allured by the selection of a judicious variety of striking and impressive objects and descriptions, to partake of those mental enjoyments which might ultimately issue in the happiest results. The man of an inquisitive turn of mind, who now throws aside everything that has the appearance of religion, on account of its dullness, might have his curiosity gratified amidst such a variety as that to which I allude; and, from perceiving the bearing of every discussion on the great realities of religion and a future state, might be led to more serious inquiries after the path that leads to immortality. In a word, to associate and to amalgamate, as it were, the arts and sciences, and every department of useful knowledge with Divine subjects, is to consecrate them to their original and legitimate ends, and to present religion to the eyes of men in its most sublime, and comprehensive, and attractive form, corresponding to what appears to be the design of the Creator, in all the manifestations he has given of himself, in the System of Nature, in the operations of Providence, and in the Economy of Redemption.

II.—*By connecting Science with Religion, Christians would be enabled to take* AN EXTENSIVE SURVEY OF THE KINGDOM OF GOD.

How very narrow and limited are the views of most professors of religion respecting the universal Kingdom of Jehovah, and the range of his operations! The views of some individuals are confined chiefly within the limits of their own parish, or at farthest, extend only to the blue mountains that skirt their horizon, and form the boundary of their sight. Within this narrow circle, all their ideas of God, of religion, and of the relations of intelligent beings to each other, are chiefly confined. There are others, who form an extensive class of our population, whose ideas are confined nearly to the county in which they reside, and to the adjacent districts; and there are few, comparatively, whose views extend beyond the confines of the kingdom to which they belong—though the whole island in which we reside is less than the two-thousandth part of the globe we inhabit. Of the vast extent of this earthly ball, of its figure and motions, of its continents, seas, islands, and oceans; of its volcanoes and ranges of mountains, of its numerous and diversified climates and landscapes; of the various nations and tribes of mankind that people its surface, and of the moral government of God respecting them,—

they are almost as completely ignorant as the untutored Greenlander, or the roving savage.—With regard to the objects which lie beyond the boundary of our world, they have no precise and definite conceptions. When the moon is "walking in brightness" through the heavens, they take the advantage of her light to prosecute their journeys; and, when the sky is overcast with clouds, and they are anxious to travel a few miles to their destined homes, they will lift up their eyes to the heavens to see if any of the stars are twinkling through the gloom, that their footsteps may be directed by their glimmering rays. Beyond this they seldom soar. What may be the nature of the vast assemblage of shining points which adorn the canopy of their habitation, and the ends they are destined to accomplish in the plan of the Creator's operations, they consider as no part of their province to inquire.

> "Their minds, fair Science never taught to stray
> Far as the Solar Worlds, or Milky Way."

How very different in point of variety, of grandeur, and of extent, are the views of the man who connects all the different departments of knowledge, and the discoveries of science, with his prospects of God's Universal Dominions and Government! With his mental eye he can traverse the different regions of the earth, and penetrate into the most distant and retired recesses where human beings have their residence. He can contemplate and adore the conduct of Divine Sovereignty, in leaving so many nations to grope amidst the darkness of Heathen idolatry,—he can trace the beams of the Sun of Righteousness, as they gradually arise to illumine the benighted tribes of men,—he can direct his prayers, with intelligence and fervor, in behalf of particular kindreds and people,—he can devise, with judgment and discrimination, schemes for carrying the "salvation of God" into effect,—he can realize, in some measure, to his mental sight, the glorious and happy scenes which will be displayed in the future ages of time, when "the kingdoms of this world shall become the kingdoms of our Lord, and of his Christ," and when the "everlasting gospel" shall be published, and its blessings distributed among all who dwell upon the face of the earth. He can bound from this earth to the planetary worlds, and survey far more spacious globes, peopled with a higher order of intelligences, arranged and superintended by the same Almighty Sovereign, who "doth according to his will among the inhabitants of the earth." He can wing his way beyond the visible region of the sky, until he find himself surrounded on every hand with suns and systems of worlds, rising to view, in boundless perspective, throughout the tracts of immensity—diversified with scenes of magnificence, and with beings of every order—all under the government and the wise direction of Him who "rules among the armies of heaven," and who "preserveth them all," and whom the "host of heaven worship" and adore. He can soar beyond them all to the Throne of God, where angels and archangels, cherubim and seraphim, celebrate the praises of their Sovereign Lord, and stand ready to announce his will by their rapid flight to the most distant provinces of his empire. He can descend from that lofty eminence to this terrestrial world, allotted for his temporary abode, and survey another unbounded province of the empire of God, in those living worlds which lie hid from the unassisted sight, and which the microscope alone can descry. He can here perceive the same Hand and Intelligence which direct the rolling worlds above, and marshal all the angelic tribes—organizing, arranging and governing the countless myriads of animated existence which people the surface of a muddy pool. He can speed his course from one of these departments of Jehovah's kingdom to another, until, astonished and overwhelmed with the order, the grandeur, and extent of the wondrous scene, he is constrained to exclaim,—"Great and marvelous are thy works, Lord God Almighty!" "Thine understanding is infinite!" The limits of thy dominions are "past finding out!"

By taking such extensive surveys of the empire of Jehovah, we are enabled to perceive the spirit and references of those sublime passages in the sacred writings which proclaim the majesty of God and the glory of his kingdom. Such passages are diffusely scattered through the inspired volume, and have evidently an extent of reference far beyond what is generally conceived by the great mass of the Christian world. The following may suffice as a specimen:—

"Thine, O Lord! is the greatness and the glory, and the majesty; for all in heaven and earth is thine! Thine is the kingdom, O Lord! Thou art exalted above all, thou reignest over all, and in thine hand is power and might.—Behold, the heaven and the heaven of heavens is the Lord's; the earth also, with all that therein is.—Ascribe ye greatness to our God; for there is none like unto the God of Israel, who rideth upon the heavens in his strength, and in his excellency in the sky. Thou, even thou art Lord alone; thou hast made heaven, the heaven of heavens, with all their host; the earth and all things that are therein; the sea and all that is therein; and thou preservest them all, and the host of heaven worshipeth thee.—He divided the sea by his power; by his spirit he hath garnished the heavens: Lo! these are only parts of his ways; but how little a portion is heard of him, and the thunder of his power who can understand? The Lord hath prepared his throne in the heavens, and his kingdom ruleth over all.—O Lord our God! how excellent is thy name in all the earth! who hast set thy glory above the heavens. When I consider thy heavens, the work of thy fingers, the moon and the stars which thou hast ordained; what is *man* that thou art mindful of him!—His kingdom is an everlasting kingdom; honor and majesty are before him; *all the inhabitants of the earth are reputed as nothing in his sight*, and he doth according to his will in the armies of heaven and among the inhabitants of the earth.—He measures the waters in the hollow of his hand; he meteth out heaven with a span, and comprehendeth the dust of the earth in a measure.—He sitteth upon the circle of the earth, and the inhabitants thereof are as grasshoppers.—I have made the earth and created man upon it; I, even my hands, have stretched out the heavens, and all their host have I commanded.—The Most High dwelleth not in temples made with hands; for the heaven is his throne and the earth is his footstool. With God is awful majesty.—Great things doth He which we cannot comprehend; yea, the Lord sitteth King forever.—Praise ye the Lord in the heavens; praise him in the hights: praise him, all his angels; praise ye him, all his hosts. Praise him, sun and moon; praise him, all ye stars of light; praise him, ye heaven of heavens. Praise him, ye kings of the earth, and all people, princes, and judges of the earth; both young men and maidens; old men and children—let them praise the name of the Lord; for his name alone is excellent, his glory is above the earth and heaven."

These sublime descriptions of the supremacy of God and of the grandeur of his kingdom, must convince every reflecting mind of the inconceivable magnificence and extent of that dominion "which ruleth over all." It is quite evident that we can never enter, with intelligence, into the full import and the grand reference of such exalted language employed by inspired writers, unless we take into view all the discoveries which science has made, both in the earth and in the heavens, respecting the variety and extent of the dominions of the Creator. If the "kingdom of the Most High" were as limited in its range as most Christians seem to conceive, such descriptions might be considered as mere hyperboles of bombast, or extravagant declamation, which far exceed the bounds of "truth and soberness." But we are certain that the conceptions and the language of mortals can never go beyond the reality of what actually exists within the boundless precincts of Jehovah's empire; for "who can utter the mighty acts of the Lord?" or "who can show forth *all* his praise?" The language and descriptions to which we have now adverted seem to have had a prospective reference to later and more enlightened times, when more extensive prospects of God's dominions would be opened up by the exertions of the human intellect. And were we to search all the records of literature, in ancient or modern times, we should find no descriptions nor language of such a dignified nature as to express the views and feelings of an enlightened Christian philosopher, when he contemplates the sublimity and extent of Divine operations—except those which are to be found in the inspired volume—the strength, and majesty, and comprehension of which no human language can ever exceed.

Again, by familiarizing our minds to such extended prospects of God's universal kingdom, we shall be qualified and disposed to comply with the injunctions of Scripture, which represent it as an imperious duty *to communicate to the minds of others such elevated conceptions.* This duty is enjoined in numerous passages of sacred Scripture, particularly in the book of Psalms: "Declare his glory among the heathen, and his wonders among all people.—I will extol thee, my God, O King.—One generation shall praise thy works to another, and shall declare thy mighty acts.—I will speak of the glorious honor of thy majesty, and of thy wondrous works.—And men shall speak of the might of thy terrible acts, and shall declare thy greatness. All thy works shall praise thee, O Lord; and thy saints shall bless thee. *They shall speak of the glory of thy kingdom, and talk of thy power; to make known to the sons of men thy mighty acts, and the glorious majesty of thy kingdom!*"* When we look around us in the world, and in the visible church, and mark the conceptions and the conversation of the members of religious societies, we need scarcely say how little this ennobling duty is attended to by the mass of those who bear the Christian name. We hear abundance of idle chat about the fashions and the politics of the day; about balls, horse-races, court etiquette, theatrical amusements, contested elections, the squabbles of corporations, sectarian contentions, and ecclesiastical feuds. We listen to slanderous conversation, and hear abundance of mean, and base, and uncharitable insinuations against our neighbors; which indicate the operation of malice, hatred, envy, and other malignant dispositions. We spend whole hours in boisterous disputations about metaphysical subtleties in religion, and questions "which gender strife rather than godly edifying:" but "to speak of the glory of God's kingdom, and to talk of his 'POWER,'" with the view of "making known to the sons of men his mighty works," is a duty which remains yet to be learned by the majority of those who profess the religion of Jesus. Even sincere Christians, while "taking sweet counsel together,"—when conversing about the love of Christ, and "the deep things of God," and when endeavoring to cheer each other's spirits with the comforts of religion—seldom or never advert to the visible works of God, and the displays of his power and beneficence, as manifested in creation, from which they might derive additional comfort and support to their faith, hope, and joy, and more expansive views of the perfections and character of their Father and their friend. And how can they be supposed to be qualified to enter into the spirit of such exercises, and to proclaim to others "the glorious majesty of God's kingdom," unless such subjects be illustrated in *minute detail*, and proclaimed with becoming energy, both from the pulpit and from the press? These powerful engines, when conducted with judgment and discrimination, are capable of producing on the mass of mankind a tone of thinking and an enlargement of conception on such subjects which no other means can easily effect; and it is to be hoped that more precise and luminous details, and more vigor and animation will soon be displayed in this respect than in the ages that are past.

There is a certain principle of *selfishness* which pervades the minds of many professed religionists, which leads them to conclude that, if they can but secure their own *personal salvation*, they need give themselves no trouble about the glory and extent of the kingdom of the Most High. "What need we care," say they, "about nations in the far-distant parts of the world, and about the planets and the stars? our business is to attend to the spiritual interests of our souls." Such persons seem neither to understand in what salvation really consists, and what is conducive to their spiritual interests, nor to appreciate those tempers and habits which will qualify them for the enjoyment of eternal life. It forms but a very slender evidence of their possessing any spark of Christianity at all, if they wish to rest satisfied with the most vague and groveling conceptions, and if they do not ardently aspire after a more enlarged view of the attributes of God, and the glory of his empire, and of whatever may tend to expand their conceptions of the "inheritance of the saints in light." We have often been astonished at the opinions of some of those who move in a higher sphere of intelligence, who seem to consider it as a matter of *pure indifference* whether or not Christians should attain to the highest conception in their power of the God whom they worship, and of his boundless dominions; because they conceive that such views are not essentially connected with salvation! But we would ask such persons how they came to know that such views are not connected with salvation! Though they may not have been essential to the salvation of men in the dark ages that are past, or to obscure tribes of people at present, who have no access to the proper sources of information, yet, since God, in the course of his providence, which guides all human inventions and discoveries, has disclosed to us a far more expansive view of the "glory of his kingdom," than former ages could obtain, for the purpose of illustrating the revelations of his word, who will dare to assert that the man who has access, by his studious efforts, to contemplate this wondrous scene, and to display its grandeur to others, and yet willfully shuts his eyes on the divine glory therein displayed, does not thereby hazard the Divine displeasure? In this point of view, the following passage deserves a serious consideration: "because they regard not the works of the Lord, nor the operations of his hands, he shall destroy them, and not build them up." We have no hesitation in admitting that persons may have obtained salvation who never saw more of the sacred writings than what is contained in the gospel of Mark, or in one of Paul's epistles; but what should we say of the man who had access to all the revelations of heaven we now possess, and yet confined his attention solely to a chapter or two in the New Testament, and would not deign to look into any other part of the inspired volume? We should not hesitate at once to pronounce that such a person was grossly deficient in his duty, and devoid of that reverence and submission which are due to the oracles of God.—And if it be admitted that the person who has access to the Bible, and who refuses to peruse its important contents, is guilty of a criminal neglect, we do not see how the man who has free access to the other volume of God's revelation, and views it as a matter of mere indifference whether he look into it or not, can be deemed in this respect entirely innocent. If it be understood that we shall be judged according to the light and privileges we enjoy, and the use we make of them in our improvement in the knowledge of God—we would deem it a hazardous position for any one to support, "That inattention to the visible glories of the kingdom of God, and to the 'declaration of his wonders among the people,' is a matter either of indifference or of trivial importance."

---

* Psalm cxlv. and xcvi. 3, 4.

For, let it be considered further, that *on the extent of our views respecting the universal kingdom of God, depends our conceptions of the majesty and glory of the Creator himself.* We become acquainted with the nature of God only in so far as he has manifested himself to us by external operations,* and in so far as we form just conceptions of these operations. If we conceive his empire as included within the bounds of eighty or ninety thousand miles, our conceptions of the Sovereign of that empire will be circumscribed within nearly the same limits. The mind of every reasonable man must indeed admit the abstract proposition, "That the Divine Being is infinite, and consequently fills all space with his presence."—But this infinity, in our view, is nothing more than *a vague conception of empty space, extending a little way beyond the sphere of his visible operations.* The mind must have some material, visible, or tangible objects to rest upon, and to guide it in its excursions when it would attempt to form the most definite and comprehensive conceptions of an infinite, eternal, and invisible existence. For, however much we may talk about purely *spiritual ideas*, it is quite evident, from the nature of things, and from the very constitution of man, that we can have no ideas at all without the intervention of *sensible objects.* And therefore, if we would wish to form the most sublime conceptions of God himself, we must endeavor, in the first place, to take the most extensive views which science and revelation exhibit of his vast dominions. We must endeavor to form some adequate idea of the wide extent of the globe on which we dwell its diversified scenery, and the numerous tribes of human beings and other animated existences, visible and invisible, which people its different provinces. We must explore the vast regions of the planetary system, and compare the bulk of the earth, large as it is, with some of those more magnificent globes which would contain within their circumference a thousand worlds as large as ours. We must next wing our way, in imagination, over a space which a cannon ball, flying five hundred miles every hour, would not traverse in ten hundred thousand years, until we arrive at the nearest fixed stars, and find ourselves in the center of thousands of systems and worlds, arranged at immeasurable distances from one another. We must pass from one nebula, or cluster of systems, to another; continuing our excursions as far as the eye or the telescope can direct our view; and, when the aid of artificial instruments begins to fail, our imagination must still take its flight far beyond the boundaries of mortal vision, and add system to system, and nebula to nebula, through the boundless regions of space, until we arrive at the grand center of the universe, the Throne of God, around which all worlds and beings revolve, where "thousands of thousands" of bright intelligences "minister to Him, and ten thousand times ten thousand stand before Him."—We must consider all this magnificent assemblage of objects, not merely as so many masses of inert matter, or as a grand raree-show, to dazzle the eyes of a few hundreds of human spectators,—but as destined for purposes worthy of the plans and the intelligence of Him who is "the only wise God,"—as peopled with numerous orders of intelligent beings, whose physical and moral economy is superintended and directed by Him who, at the same time, rules amidst the tumults of human revolutions, and governs the living myriads which people a drop of water.

In this way, then, do we come to acquire the most extensive views of the amplitude and glory of the kingdom of the Most High; and it is only by the same process of thought that we can ever attain the most exalted conceptions of the attributes of its Almighty Sovereign. For our views of the Sovereign of the universe must always correspond with our views of the extent and magnificence of those dominions which sprung from his Creating Hand, and over which he every moment presides. His essence must forever remain imperceptible to finite minds; for He is "the King Eternal, Immortal, and *Invisible*, dwelling in that Light which no man can approach unto, whom no man hath seen, or *can see.*" From his nature, as a spiritual uncompounded substance, and from his immensity, as filling infinite space with his presence, it appears impossible, in the very nature of things, that the glory of his perfections can be displayed in any other way than through the medium of the visible operations of his hands, or in the dispensations of his providence toward particular worlds or classes of intelligences. And if, in the future world, the souls of good men shall enjoy a more glorious display than at present of the attributes of Deity, it will be owing chiefly to their being placed in more favorable circumstances than they now are for contemplating this display; to their faculties being more invigorated; and every physical and moral impediment to their exercise being completely removed; so as to enable them to perceive more clearly than they now do the unbounded displays he has given of his infinite Power, Wisdom, and Benevolence. And, if we expect to be introduced to this state of enlarged vision when we pass from the scenes of mortality, it cannot be a matter of *mere indifference*, even now, whether or not our minds be prepared for such exalted employments, by endeavoring to form the most ample conceptions of the attributes of God which can be obtained through the medium of his Word, and by a contemplation of the variety and magnificence of his Works.

---

* Here I include the manifestation of Deity as exhibited both in Divine Revelation and in the system of Nature

In the prospect of that world where we hope to spend an interminable existence, it must also be interesting to ascertain, whether or not the dominions of the universal Sovereign present such an extent of empire, and such a variety of objects, that new scenes of wonder and glory may be expected to be displayed in continual succession, for the contemplation and entertainment of holy beings, while eternal ages are rolling on. And, on this point, the discoveries of science confirm and illustrate the notices of heavenly glory and felicity recorded in the inspired Volume, and lead us to rest with full assurance on the prophetic declaration, that "eye hath not seen, nor ear heard, nor hath it entered into the heart of man to conceive, the things which God hath prepared for them that love him."

III.—*By connecting the Discoveries of Science with Religion, the minds of Christians would be enabled to take a more minute and comprehensive survey of the* OPERATIONS OF PROVIDENCE.

Providence is that superintendence and care which God exercises over all creatures and events, in order to accomplish the eternal purposes of his will. In *Creation*, God brought the universe out of nothing, and arranged all its provinces and inhabitants into due order. By his *Providence*, he supports and governs all the movements of the material system, and the sensitive and rational beings with which it is peopled. It is evident, that, in proportion as our views of the Creator's Dominions are extended, our views of his Providence will, to a certain extent, be proportionably enlarged. For, wherever worlds and beings exist, there will God be found preserving, superintending, and governing the movements of all creatures and events. It is chiefly, however, in the world in which we reside, that the diversified dispensations of Providence can be distinctly traced. Now, an acquaintance with the prominent parts of the different branches of knowledge to which I have already adverted, would enable us to take a particular and comprehensive view, not only of the ways of God to man, but also of his arrangements in reference to all subordinate creatures and events.

From the Inspired History of the Old Testament, we can trace the prominent lines of the dispensations of God toward man, particularly in regard to the Israelites and the surrounding nations—from the Creation to a period about 400 years before the coming of Christ. But in order to perceive the further progress and bearings of these lines until the commencement of the New Testament economy, we must have recourse to the most authentic records of profane history. From the era of the birth of Christ to near the close of the first century, we can acquire, from the Evangelists, and the History of the Apostles, a particular account of the life of Christ, of the events which preceded and accompanied the finishing of the work of redemption, and of the progress of the Gospel through Judea, and the adjacent countries. But, after this period, we have no *inspired* guide to direct us in tracing the Divine dispensations toward the various nations of the earth; and therefore we must have recourse to the annals, memoirs, chronicles, and other records of the history of nations, down to the period in which we live; otherwise we could never contemplate the continued series of events in the Divine economy toward the inhabitants of our world. Unless men of learning and of observation had recorded the prominent facts which have occurred in the history of nations, for 1700 years past, we must have remained almost as ignorant of the dispensations of God toward our race, during that period, as the inhabitants of the planet Saturn; and unless we study the events thus recorded in the writings of the historian, and contemplate their various aspects and bearings in the light of Divine Revelation, we must still remain ignorant of the grand movements and tendencies of Divine Providence. This single circumstance shows, in the clearest light, that it is the intention of God, that we should learn the operations of his Providence from the researches of Science and of History, as well as from the records of Revelation; and that the Scriptures, though they contain every *supernatural* discovery requisite to our happiness, are not of themselves sufficient to present us with a connected view of the prominent dispensations of Heaven, from the Creation to the period in which we live.

From the science of *Geography*, we acquire a knowledge of the extent of the surface of the earth—of the various tribes of human inhabitants with which it is peopled—of the physical aspect of the different climates they inhabit—of their arts, manners, customs, laws, religion, vices, wars, and political economy: and, consequently, we can, in these and similar respects, trace some of the aspects of Divine Providence toward them in relation to their present and future condition. From the same source, we learn the number of human beings which the Governor of the world has under his direction at one time, which is nearly a thousand millions, or about four hundred times the number of the inhabitants of Scotland. From the data afforded by this science, we may also form an estimate of the number of disembodied spirits that have passed from this world since the creation, and are now under the superintendence of the Almighty in the invisible state, which cannot be much less than 145,000 millions; and, on similar grounds, we may also learn the number of rational beings that are coming forward into existence, and passing into the eternal world every day, which is at least 68,000, and consequently nearly 50 during each passing minute,—every individual of which the Supreme Disposer of events superintends at his entrance into life; and, at his departure from it, directs to his respective and eternal state of destination. Hence it follows, that, could we take a view of the whole system of animation on our globe with the eye of Omniscience, or even with the penetrating glance of an angelic being, we should behold *every hour*, thousands of human and other animated beings incessantly emerging into existence, and thousands, at the same time, departing into an unseen world, under a vast diversity of circumstances; and this succession and exit of human beings will incessantly go forward from age to age, until all the designs of Providence in relation to our world be fully accomplished. All which circumstances, and many others of a similar kind, must be taken into account, in order to our forming a comprehensive conception of the numerous bearings, and the incessant agency of a Superintending Providence.

From *Natural History*, we learn the immense number and variety of the subordinate tribes of animated beings which inhabit the different regions of earth, air, and sea—their economy and instincts—their modes of existence, and the manner in which the Creator provides for their various necessities. From an acquaintance with the *History of the Arts and Mechanical Inventions*, we learn the gradual manner in which God directs the movements of the human mind, in making those improvements and discoveries which have a bearing upon the accomplishment of his eternal plans of mercy, and which tend to enlarge our views of the amplitude and the glories of his kingdom.—From *Natural Philosophy* and *Chemistry*, we learn the secondary causes or subordinate laws by which the Almighty supports and directs the natural constitution of the world—the wonderful manner in which our lives are every moment supported—and the agencies by which fire, air, light, heat, and fertility are distributed through the globe, for promoting the comfort and happiness "of everything that lives."—From *Anatomy* and *Physiology*, we learn how "fearfully and wonderfully we are made and preserved"—that our health and comfort depend upon the regular action of a thousand organical parts and functions over which we have no control—and that our very existence every moment is dependent on the superintendence of a Superior Power, "in whose hand our breath is, and whose are all our ways."

By an occasional study, then, of the subjects to which we have now alluded, we might gradually expand our conceptions of the range and operations of Divine Providence. Every geographical exploration of a new region of the globe—every scientific improvement and discovery—every useful invention—every eruption of a volcano—every shock of an earthquake—every hurricane, and storm, and tempest—every battle of the warrior—every revolution among the nations—and every detail in the newspapers we daily read, would lead us to form some conceptions of the providential purposes of Him who is the Supreme Disposer of all events.—Even the arrangements of Divine Wisdom, with regard to the economy of the lower animals, ought not to be overlooked in such a survey. When we consider the immense number and variety of animated beings--that there are 600 species of quadrupeds, every species containing, perhaps, many millions of individuals; 4000 species of birds; 3000 species of fishes; 700 species of reptiles; and 44,000 different kinds of insects, beside many thousands of species altogether invisible to the unassisted sight--when we consider that the structure and organization of all these different species are different from each other, and exactly adapted to their various situations and modes of existence, and that their multifarious wants in regard to food and habitation, are all provided for, and amply supplied by Him, who, at the same time, arranges and governs the affairs of ten thousand worlds—we must be lost in astonishment at the greatness of the Intelligence which formed them, and at the exuberance of that bounty which spreads so full a table for so immense an assemblage of living beings! And were we transported to other worlds, we should, doubtless, behold still more ample displays of Divine Beneficence.

We are here presented with a striking commentary on such passages of the Sacred Volume as these: "The eyes of all look unto thee, O Lord! and thou givest them their meat in due season. Thou openest thy hand liberally, and satisfiest the desire of every living thing. The earth is full of thy riches, O Lord! so is the great and wide sea, wherein are things creeping innumerable, both great and small beasts. These all wait upon thee, and thou givest them their meat in due season. That which thou givest them they gather: Thou openest thine hand, they are filled with good."—"O Lord, thou preservest man and beast! How excellent is thy loving-kindness! Therefore the children of men shall put their trust under the shadow of thy wings. They shall be abundantly satisfied with the fatness of thy house"* (of the table thou hast spread in thy world for all thine offspring), "and thou shalt make them drink of the river of thy pleasures." One excellent practical effect which might flow from such contemplations would be to inspire us with feelings of humanity toward the inferior order of animals, and to prevent us from wantonly and unnecessarily torturing, or depriving them of existence. For, since the Creator and Preserver of all has so curiously organized their bodies, and fitted them for the different regions in which they reside, and so carefully provided for all their wants, it must be His will that they should enjoy happiness according to the extent of their capacities; and, therefore, they ought to be considered as necessary parts of our sublunary system.—Another practical lesson we may derive from such surveys, is, to place an unshaken dependence upon God for our temporal subsistence, while we, at the same time, exert all our faculties in the line of active duty. "Blessed is the man who trusteth in him; for there is no want to them that fear him. The young lions may suffer hunger, but they that fear the Lord shall not want any good thing."—He who decks the lily of the vale, and spreads out a plentiful table to the fowls of heaven, to the beasts of the forest, to the creeping insect, and even to the microscopic animalcule, will never fail to supply the necessary wants of those who "do His will, and hearken to the voice of His commandments." And if at any time we be found destitute of daily food, and pining away in penury and squalid disease, we have too much reason to conclude, that in one way or another, either our deviation from the path of rectitude, or our distrust of Divine Providence, or our want of prudence and economy, has procured for us these things.

I have said, that it is chiefly in the world in which we dwell that the dispensations of Providence can be distinctly traced. But we must, nevertheless, admit, that the care and superintendence of God are as minutely exercised in the distant regions of the universe, as in our terrestrial sphere; though we are not permitted, at present, to inspect the particular details of His procedure in reference to other orders of intelligences. We are not, however, altogether ignorant of some prominent features of the physical and moral economy of other worlds, in consequence of the discoveries of modern astronomical science.

With respect to their *physical* economy, we behold a striking variety in the Divine arrangements We perceive one planetary world surrounded by two splendid and magnificent rings, one of them 204,000, and the other 184,000 miles in diameter, stretching across its celestial canopy from one end of the heavens to another—moving with majestic grandeur around its inhabitants every ten hours, and diffusing a light equal to several thousands of moons like ours—which may be considered as a visible and permanent emblem of the Majesty and Glory of their Creator. We perceive, connected with the same globe, seven moons all larger than ours, of different magnitudes, and placed at different distances, and revolving in different periods of time around that spacious world. The diversified aspects of these rings, as viewed from the different regions of the planet at different times, and the variety of appearances produced by the alternate rising, setting, culmination, and frequent eclipses, and other aspects of the moons, must present to the inhabitants a very grand, and diversified, and magnificent scene of Divine operation.* On the other hand, we behold another planetary globe destitute both of rings and moons, but which has the starry heavens presented to view nearly in the same aspect in which we behold them. We perceive a third globe much larger than them both, capable of containing 200 times the number of the inhabitants of our world—accompanied in its course with four moons to diffuse light in the absence of the sun, and to diversify the aspect of its sky. In some of these worlds, the succession of day and night is accomplished within the space of ten hours; in others, this revolution is not completed until after the lapse of twenty-four hours, or of as many days. In some, the days and nights are nearly equal on every part of their surface, and they have little variety of seasons; in others, the variety in the length of the days and the vicissitudes of the seasons, are nearly the same as those we experience in our terrestrial world. Around some, there appears a dense atmosphere, while others are environed with atmospheres more rare and transparent. Some move in the vicinity of the sun, and enjoy an abundant efflux of light and heat, while others are removed to the distance of eighteen hundred millions of miles from that central luminary. Some finish the revolution of their year in a few months; while others require twelve, thirty, or even eighty of our years to complete their annual round. Some appear adorned with majestic mountain scenery, and others seem to have great changes occasionally taking place in their atmospheres, or on their surfaces. There are four planetary bodies lately discovered, which, there is every reason to believe, once formed the component parts of a larger globe; but, by some mighty catastrophe in the dispensations of Heaven, it appears to have been burst asunder into the fragments we now behold. If the general proposition illustrated in Section II of the preceding chapter be admitted, such a fact would seem to indicate, that a moral revolution has taken place among the intelligent beings who had originally been placed in those regions; and that their fate was involved in the dreadful shock which burst asunder the globe they inhabited, just as the fate of the Antediluvians was involved in the shock by which the solid crust of our globe was disrupted, at the period of the universal deluge.

---

* This and several other similar passages, may be considered as more especially applicable to the bounty of Providence which God has provided for all his creatures. The practice of *spiritualizing* such passages, as it is termed, has a tendency to caricature Scripture, and to twist it from its precise and sublime references, to accord with the vague fancies of injudicious minds. The literal meaning of Scripture is always the most appropriate, emphatic, and sublime, but it may, in some cases, be used by way of accommodation, in illustrating divine subjects when it is applied with judgment and discrimination.

These are some outlines in the economy of Providence which we can trace with regard to the arrangements of other worlds; but beyond such general aspects we are not permitted to penetrate, so long as we sojourn in tabernacles of clay. But even such general views afford some scope to the contemplative mind, for forming enlarged conceptions of the Grandeur and Diversity of the Dispensations of God, in the worlds which roll in the distant regions of space.

With regard to their *moral economy*—we may rest assured, that the prominent outlines of it are materially the same as of that economy which relates to the inhabitants of our world. The fundamental principles of the moral laws given to men, and which it is the great object of Revelation to support and illustrate, are, "Thou shalt love the Lord thy God with all thy heart and understanding," and, "Thou shalt love thy neighbor as thyself." On these two commandments hang all the Law and the Prophets.—Now we must at once admit from the Nature of the Divine Being, and from the relation in which rational beings stand to Him, and to one another,—that the Creator has enacted these laws, as the great governing principles by which the actions of all intelligences in heaven, as well as upon earth, are to be directed. For the governor of the world can never be supposed to issue a law to any order of rational creatures, which would permit them to *hate* their Creator, or to hate those whom he has formed after his own image. Such a supposition would be inconsistent with the eternal rules of rectitude, and with the perfections of Deity; and the fact supposed (if it could exist), would introduce confusion and misery throughout the whole intelligent universe. And, therefore, we must necessarily admit, that the laws to which I now advert, are binding upon all the rational inhabitants which exist throughout Jehovah's dominions; and that it is by these that the moral order of all the Principalities and Powers of Heaven is preserved and directed. In those worlds where there is no change in the succession of their inhabitants—or, in other words, where there is no death, or where they are not produced by any process analogous to generation, but have a fixed and permanent residence — there will be no need for moral precepts corresponding to the fifth and seventh commandments of our moral law; and, in those worlds where property is common, and the bounties of the Creator are equally enjoyed by all, there will be no necessity for a law corresponding to the eighth commandment; but the general principles on which these laws are founded, will be applicable to all the other circumstances and relations which actually exist: so that the *principle*, and *spirit*, and *essence* of our religion, must be common to all the holy inhabitants of the universe. And, therefore, it will follow, that every intelligent being that is animated and directed by such principles and affections, will be qualified for holding delightful intercourse with all holy beings throughout the universe of God, in whatever province of the Creator's empire he may hereafter be placed; and, to qualify us for such harmonious and affectionate intercourses, is one great end of the Salvation exhibited in the Gospel. So that, although we cannot, in our present state, acquire a minute and comprehensive knowledge of the moral history of other worlds, of the special interpositions or manifestations of Deity in relation to them, or of the means by which they are carried forward in moral and intellectual improvement—yet we can trace the *general* principles or laws which form the basis of their moral and religious economy. For, as the laws of optics, and the principle of gravitation, pervade the whole material system, as far as the universe is visible to our unassisted vision—so the principle of supreme love to God, and sincere affection to fellow-intelligences, must pervade the *intellectual* universe wherever it extends; and, if any intelligent agents beside men have violated these laws, they must experience pain, and misery, and disorder, analogous to those which are felt by the inhabitants of our apostate world.

---

* See the Frontispiece, Fig. 7.

Thus I have endeavored to show, that the combination of Science with Religion, would tend to expand our views of Divine Providence—in the various arrangements of God, in relation to the human race, and to the subordinate tribes of sensitive beings—and in reference to some of the prominent features of his administration in distant worlds. And, therefore, though the Christian ought never to overlook the ways of Providence in relation to himself, and to his spiritual and domestic concerns, yet it would argue a selfishness and a sottishness, altogether inconsistent with the noble and expansive spirit of Christianity, to overlook all the other parts of the Theater of Divine Dispensations, when a very slight degree of labor and research might be instrumental in unfolding them to his view

IV.—*The connection of Science with Religion would have a tendency to induce upon Christians* A SPIRIT OF LIBERALITY, *of* CANDOR, *and of* ACCURACY IN JUDGING OF THE OPINIONS AND ACTIONS OF MEN, *and of* THE DIVINE PROCEDURE AND OPERATIONS.

Who is the most Candid and Liberal Being in the universe? God.—And why is God to be considered as the most Liberal Intelligence that exists? Because He embraces a minute, a full, and comprehensive view of all the circumstances, connections, relations, habits, motives, temptations, modes of thinking, educational biases, physical affections, and other causes, that may influence the sentiments or the conduct of any of his creatures.—Who, among created intelligences may be viewed as endowed with these qualities in the next degree? The loftiest seraph that God has created, who has winged his way to numerous worlds; and taken the most extensive survey of the dispensations of the Almighty, and of all creatures and events.—Who, among the sons of men, is the most illiberal and inaccurate in judging of opinions, of persons, and of things? The man who has lived all his days within the smoke of his father's chimney, or within the confines of his native village—who has never looked beyond the range of his own religious party—whose thoughts have always run in one narrow track—whose reading has been confined to two or three musty volumes, which have lain for ages on the same smoky shelf—who cares for nothing either in the heavens or the earth, but in so far as it ministers to his convenience, his avarice, or his sensual enjoyment—who will admit no sentiment to be true, but what he may have heard broached by his parson—and whose conversation seldom rises beyond mere gossiping chit-chat, and the slanderous remarks which are circulated among his neighbors. Such characters are entirely unqualified for forming a correct judgment, either of the sentiments and the actions of men, or of the works and the ways of God; for they are completely destitute of the requisite *data* whereon to form a rational decision in relation to either of these subjects.

It may be admitted as a kind of axiom, in our estimate of human character, that, in proportion to the ignorance, and the narrow range of view, which characterize any individual, in a similar proportion will be his want of candor, and his unfitness for passing a sound judgment on any subject that is laid before him—and that the man who has taken excursions through the widest range of thought, accompanied with a corresponding improvement of his moral powers, will always be the most liberal and candid in his decisions on the moral and intellectual qualities of others. To these maxims, few exceptions will generally be found.—In forming an enlightened judgment in regard to any action or object, it is essentially requisite, that we contemplate it in all its different features and aspects, and in all its minute circumstances, bearings, and relations.—We would not hesitate for a moment to determine who is best qualified to give an accurate description of a city,—he who has only viewed its spires from a distance, while in rapid motion in his chariot—or he who has minutely surveyed all its streets, lanes, squares, public edifices, and surrounding scenery, in every variety of aspect; or, who appears most likely to form the most accurate and enlightened judgment in relation to any particular kingdom,—he who has just skirted along a few miles in one of its coasts, or he who has traversed its length and breadth in all directions, and mingled with every class of its inhabitants. On the same principle it must be admitted, that he who has viewed religion in all its aspects and bearings, who has taken the most extensive survey of the manifestations of God, and of the habits and relations of men, is the best qualified to pronounce a candid and accurate decision on all the intellectual and moral cases that may come before him.

If the spirit of the above-stated sentiments be founded on reason and on fact, it will follow that, the more we resemble God in the amplitude of our intellectual views and benevolent affections, the more candid, and liberal, and accurate will our judgments be in reference to all the actions, objects, and relations we contemplate. On the other hand, the man who is confined to a narrow range of thought and prospect, is continually blundering in the estimates he forms, both in respect to physical facts, to general principles, and to moral actions. He forms a premature and uncharitable opinion on every slander and report against his neighbor. He condemns without hesitation, and throws an unmerited odium on whole bodies of men, because one or two of their number may have displayed weakness and folly. He hates and despises men and their opinions, because they belong not to his political or religious party. He pronounces his decisions on the motives of men with as much confidence as if he had surveyed their hearts with the eye of Omniscience. He cannot hear an objection against his favorite opinions with patience, nor an apology for any set of principles but his own. He is arrogant and dogmatical in his assertions, and will make no concessions to the superior wisdom of others. He sets himself, with violence, against every proposal for reformation in the church, because his forefathers never thought of it, and because such "innovations" do not suit his humor and preconceived opinions. He decides, in the most confident tone, on what God *can* and *cannot* do, as if he had taken the gauge of infinite perfection; and he frets at the Divine dispensations when they do not exactly quadrate with his own humors and selfish views.

With regard to the operations of the Most High he also forms the most foolish, and vague, and contradictory conceptions. Tell him of the vast dimensions of the planetary system, of the men and animals that live on the opposite side of the globe, of the annual and diurnal motion of the earth—that this world and its inhabitants are moving through the regions of space many thousands of miles every hour—that one of the planets is so large that it would contain 1400 worlds as spacious as ours—that, another is flying through the tracts of immensity at the rate of a hundred thousand miles an hour—and that light is darted from the sun at a velocity of 192,000 miles in a moment of time,—he will stare at you with astonishment at such extravagant assertions, and will sooner believe the stories of giants 100 feet high, and of fairies that can enter in crowds through the keyhole of his door. Instead of frankly acknowledging that "he is ignorant of such subjects, and of the grounds of such conclusions—that those that have studied them with intelligence are best capable of judging — that, if true, they must fill us with admiration of the glory of God—but that, as he has hitherto had no opportunity of examining such matters, he must suspend his assent until he inquire into the reasons which can be given for such amazing deductions;" instead of such concessions, which are the dictates of modesty and of common sense, he will tell you at once, without hesitation, and without a blush at his presumptuous decisions, that "it is all extravagance, and folly, and idle romance, contrary to Scripture, and reason, and common sense;" and will not hesitate to brand you as a heretic, for endeavoring to break loose his intellectual trammels!—thus tacitly declaring that he is far better qualified to pronounce a decision on such topics than all the philosophers and divines, and all the brightest geniuses who have appeared in the world for ages past; though he will at the same time admit, that he never gave himself the trouble to examine into such matters!

His views of the providential dispensations of God are equally partial and distorted. If disease, or poverty, or misfortune, happen to his neighbor, especially if he had withdrawn from the religious party to which he belongs, it is considered as a penal judgment for his error and apostasy. If prosperous circumstances attended his family or his religious party, it is viewed as a sign of Divine approbation. He seldom views the hand of God, except in uncommon occurrences, and then, he imagines that a miracle is performed, and that the wheels of nature are stopped in order to accomplish the event. He seldom looks beyond the precincts of his own church or nation, to observe the movements of the Divine footsteps toward other tribes of his fallen race. He overlooks the traces of Divine operation which are every moment to be seen above and around him—and yet, in the midst of all such partial and contracted views, he will sometimes decide on the Wisdom and Rectitude of the Ways of God, with as much confidence as if he had entered into the secret councils of the Eternal, and surveyed the whole plan of his procedure.

Such are a few prominent outlines of the character of thousands, whose names are enrolled as members of the visible church—whose illiberality and self-conceit are owing to the contracted notions they have formed of God and of Religion. And, surely, it must appear desirable to every enlightened Christian, that every proper mean should be used to prevent rational immortal beings from remaining enchained in such mental thraldom.

On the other hand, the man who takes an enlightened view of all the works and dispensations of God, and of all the circumstances and relations of subordinate beings, necessarily acquires a nobleness and liberality of mind, and an accuracy in judging of things human and divine, which no other person can possess. He does not hastily take up an evil report against his neighbor; for he considers how unfounded such reports often are, and how much they are owing to the insinuations of envy or of malice. And, when he can no longer doubt of an evil action being substantiated against any one, he does not triumph over him in the language of execration; for, he considers all the circumstances, relations, feelings, and temptations with which he may have been surrounded; he considers, that he himself is a frail sinful creature, and might possibly have fallen in a similar way, had he been placed in the same situation. He does not trumpet forth the praises of a man who has performed *one* brilliant benevolent deed, as if he were a character to be admired and eulogized—while the general course of his life is marked with vice, and an utter forgetfulness of God and Religion; nor does he fix a stigma of immorality upon the person who may have acted foolishly or sinfully in one or two instances, while the general tenor of his conduct has been marked by purity and rectitude: for, in both cases he considers, that it is not an *isolated action*, but *general habits* which determine the character of any individual. He esteems the Wise and the Good, and holds friendly intercourse with them, to whatever political or religious party they belong. He can bear, with affability and candor, to have his opinions contradicted, and can differ from his neighbor in many disputed points, while, at the same time, he values and esteems him. He will not brand a man as a Heretic or a Deist, because he takes a view of some dogmas in Theology in a different light from what he himself does; for he considers the difference of habits, studies, pursuits, and educational prejudices, which must have influenced his opinions; and makes due allowance for the range of thought to which he may have been accustomed. He is always disposed to attribute the actions of others to good motives, when he has no proof to the contrary. He uses no threats nor physical force to support his opinions, or to convince gainsayers; for he knows that no external coercion can illuminate the mind, and that the strength of arguments, and the force of truth, can alone produce conviction. He is convinced how ignorant he is, notwithstanding all his study, observations, and researches, and presses forward, as long as he lives, to higher degrees of knowledge and of moral improvement.

He is an active promoter of every scheme that tends to enlighten and meliorate mankind, and to extend the knowledge of salvation to the ends of the earth; for he considers that it is not by miracles, but by the subordinate agency of intelligent beings, that God will effectuate the illumination and the moral renovation of our apostate race. He views the special agency of God in all the movements of the Scientific, the Religious, and the Political world, and perceives Him accomplishing his purpose, in the inventions of human genius, and in the economy of the minutest insect, as well as in the earthquake, the storm, and the convulsions of nations; for he considers the smallest atom, and the Hosts of Heaven, as equally directed by Eternal Wisdom, and equally necessary in the universal chain of creatures and events. He displays a becoming modesty in speaking of the ways and the works of God. When he meets with any dark and afflictive dispensation in the course of Providence, he does not fret and repine, but is calm and resigned, conscious that he perceives only a small portion of the chain of God's dispensations, and is, therefore, unable to form a just comparison of the connection of any one part with the whole. When he contemplates the depraved and wretched condition of the greater part of the world, at present, and for thousands of years past, notwithstanding the salvation which has been achieved for sinners of mankind, he is far from arraigning the Divine goodness and rectitude, in leaving so many nations "to walk in their own ways;" for he knows not what relation this dismal scene may bear, what influence it may have, or what important impressions it may produce, on worlds and beings with which we are at present unacquainted.

He is cautious in pronouncing decisively respecting the dispensations of God, *in regard to the universe at large.* He does not, for example, assert, with the utmost confidence, as some have done, "that there never was, and never will be, to all the ages of eternity, such a bright display of the Divine Glory as in the Cross of Christ." He admires and adores the Condescension and the Love of God, in the plan of Salvation which the Gospel exhibits, and feels an interest in it far beyond that of any other special manifestation of Deity; but he dares not set limits to the Divine Attributes and Operations. He considers himself at present, with regard to the grand system of the Universe, in a situation similar to that of a small insect on one of the stones of a magnificent edifice, which sees only a few hairbreadths around it, and is altogether incapable of surveying the symmetry, the order, and beauty of the structure, and of forming an adequate conception of the whole. He considers that he has never yet surveyed the millionth part of Jehovah's empire, and, therefore, cannot tell what the Eternal Sovereign has been pleased to exhibit in its numerous provinces; and, least of all, can he ever presume to dive into the depths of interminable ages, and boldly declare what the Almighty will, or will not do, through eternity to come. He, therefore, views it as presumption, while he has no dictate of revelation for his warrant, to pronounce decisively, either on the one side or on the other, of such a deep and important question, which seems above the reach of the loftiest seraph to determine.* In short, he endeavors to take a view of all the manifestations of Deity within his reach, from every source of information which lies before him, and as far as his limited faculties will permit. He does not call in question the discoveries of Science, because they bring to his ears most astonishing reports of the Wisdom and Omnipotence of Jehovah; and of the boundless extent of his Kingdom; but rejoices to learn, that the grandeur of his dominions is actually found to correspond with the lofty descriptions of Divine Majesty and Glory recorded in the Volume of Inspiration, and is thereby inspired with nobler hopes of the glory and felicity of that heavenly world where he expects to spend an endless existence.

If, then, such be some of the features in the character of the enlightened Christian; if liberality and candor, and accurate investigation, mark the judgments he pronounces on the sentiments and the actions of men, and on the works and the ways of God; and if such views and feelings ought to be considered as more congenial to the noble and benevolent spirit of our religion, than the narrow and distorted notions of a contracted mind,—it must be an object much to be desired, that the mass of the Christian world be led into such trains of thought, as might imbue their minds with a larger proportion of this spirit. And, if diversified and occasional discussions on the topics to which we have adverted would have a tendency to produce this desirable effect, it is obvious, that such branches of knowledge as are calculated to enlarge the capacity of the mind, and to throw a light over the revelations and the works of God, should no longer be overlooked in the range of our religious contemplations.

V.—*The extensive range of thought which the diversified objects in Nature present,* WOULD HAVE A TENDENCY TO INSPIRE US WITH A SPIRIT OF PIETY AND PROFOUND HUMILITY.

It is owing, in many instances, to want of attention to the impressive displays of Wisdom and Omnipotence in the material world, that our pious feelings and devotional exercises are so cold and languid. We stalk about on the surface of the earth, and pass from one day to another, without reflecting on the grand and complicated machinery around us, which is carrying us along through the regions of space, and from one portion of duration to another, as if the mighty energies of the Eternal Mind, exerted in our behalf, were unworthy of our acknowledgment or regard. How few, for example, reflect, when they open their eyes in the morning, and perceive the first beams of the rising sun, that, since they lay down to sleep, the Divine Power has been exerted in carrying them more than four thousand miles round to the eastward, in order that they might again be cheered with the morning light; and that, during the same period, they, along with the earth and its vast population, have been carried forward 476,000 miles from that portion of space which they occupied seven hours before?* Or, if they have no idea of the motion of the earth, and attach no belief to such an opinion, how is it they do not reflect, that, after night has thrown its shades around them, the sun, and ten thousand other vast globes, must move several hundreds of millions of miles, before their eyes can again behold the light of day! Either the one or the other of these cases *must be the fact;* and, in either case, there is presented to our view, a display of the Omnipotence and the Superintendence of Him in whom we live and move, which demands our gratitude, our admiration, and praise. And can it ever be supposed, that such reflections, combined with all the other excitements to reverence and gratitude, will not tend to elevate our contemplations, and to raise our pious feelings to a higher pitch of devotion? Whether the Psalmist entertained any views of this kind, when he composed the ninety-second Psalm, we cannot certainly determine; but I presume, the pious and contemplative mind, when awakening from the slumbers of the night, under such impressions, might sing the first part of that song of praise with peculiar emphasis and delight—"It is a good thing to give thanks to Jehovah, and to sing praise to thy name, O thou Most High! to show forth thy loving-kindness in the morning. For thou, Lord, hast made me glad through thy work" (or thy powerful energy),—"I will triumph in the works of thy hands. O Lord! HOW GREAT ARE THY WORKS! and thy thoughts" (or contrivances) "are very deep! A brutish man knoweth not, neither doth a fool understand this."

---

* See Appendix, Note XII.

* When it is here said that we are carried "more than 4000 miles round to the eastward" during the hours of sleep —the author refers to the *diurnal* motion of the earth from west to east. The rate of this motion is different to the inhabitants of different latitudes. At the Equator the inhabitants are carried at the rate of 1038 miles an hour, and if 7 hours be allowed for nightly repose, they are carried round 7266 miles during sleep. Those who live in the 52d degree of latitude, as the inhabitants of places near London, move at the rate of 637 miles an hour; and, consequently, in the course of 7 hours, are carried round 4459 miles. The inhabitants of Greenland, in lat. 69°, during the same time, move only 2570 miles; and, were there any inhabitants at the 88th degree of latitude, or within two degrees of the polar points their motion, during 7 hours, would not exceed 252 miles.—When it is said we are carried forward during the same time, 476,000 miles, the reference is to the *annual* motion of the earth, which is at the rate of sixty-eight thousand miles every hour, and consequently 476,000 miles during the 7 hours supposed to be allotted to sleep.

An extensive acquaintance with nature and science, combined with Christian principle, would also induce *profound humility*. The man who has made excursions through the most diversified regions of thought, is deeply sensible of the little progress he has attained, and of the vast and unbounded field of divine science which still remains to be explored. When he considers the immense variety of sublime subjects which the Volume of Inspiration exhibits, and of which he has obtained but a very faint and imperfect glimpse—the comprehensive extent, and the intricate windings of the operations of Providence, and the infinite number of beings over which it extends—the amplitude and magnificence of that glorious universe over which Jehovah presides, and how small a portion of it lies open to his minute inspection—he is humbled in the dust at the view of his own insignificance; he sees himself to be a very babe in knowledge; and, as it were, just emerging from the gloom of ignorance into the first dawnings of light and intelligence. He feels the full force and spirit of the poet's sentiment—

> 'Much learning shows *how little* mortals know."

When he considers the comprehensive extent of the Divine law and its numerous bearings on every part of his conduct, and on all the diversified relations in which he stands to his God, and to his fellow-men; and when he reflects on his multiplied deviations from that eternal rule of rectitude, he is ashamed and confounded in the presence of the Holy One of Israel; and on a review of his former pride and self-conceit, is constrained to adopt the language of Agur and of Asaph—"Surely I am more brutish than any man, and have not the understanding of a man." "So foolish was I, and *ignorant*, I was as a beast before thee." He views the meanest and the most ignorant of his species, as but a very few degrees below him in the scale of intelligence, and sees no reason why he should glory over his fellows.

This sentiment might be illustrated from the example of some of the most eminent men in whose minds science and religion were combined. The Honorable Mr. BOYLE was the most unwearied and successful explorer of the works of God, in the age in which he lived, and all his philosophical pursuits were consecrated to the service of Religion. Among the excellent traits in his character, HUMILITY was the most conspicuous. "He had about him," says Bishop Burnet, "all that unaffected neglect of pomp in clothes, lodging, furniture, and equipage, which agreed with his grave and serious course of life," and was courteous and condescending to the meanest of his fellow-men. "He had," says the same author, "the profoundest veneration for the great God of heaven and earth that ever I observed in any person. The very *name* of God was never mentioned by him without a pause, and a visible stop in his discourse; and the tenor of his philosophical and theological writings is in complete unison with these traits of character.—Sir ISAAC NEWTON, too, whose genius seemed to know no limits but those of the visible universe, was distinguished by his *modesty*, *humility*, and *meekness* of temper. He had such a *humble* opinion of himself, that he had no relish of the applause which was so deservedly paid him. He would have let others run away with the glory of his inventions, if his friends and countrymen had not been more jealous of his honor than he was himself. He said a little before his death, "I do not know what I may appear to the world, but to myself I seem to have been only like a boy playing on the sea-shore, and diverting myself in now and then finding a pebble or a prettier shell than ordinary, while the great ocean of truth lay all undiscovered before me."

The same sentiment might have been illustrated from the lives of Bacon, Locke, Dr. Boerhaave, Hervey, Nieuwentyt, Ray, Derham, the Abbe Pluché, Bonnet, and other eminent characters, who devoted their stores of knowledge to the illustration of the Christian system. For an *extensive* knowledge of the operations of God has a *natural tendency* to produce humility and veneration; and wherever it is combined with pride and arrogance, either among philosophers or divines, it indicates a lamentable deficiency, if not a complete destitution, of Christian principle, and of all those tempers which form the bond of union among holy intelligences. After the attention of Job had been directed to the works of God, and when he had contemplated the inexplicable phenomena of the Divine agency in the material world, he was ashamed and confounded at his former presumption; and, in deep humility, exclaimed, "I have heard of thee by the hearing of the ear; but now mine eye seeth thee; wherefore I abhor myself, and repent in dust and ashes."—In accordance with what has been now stated, we find, that the most exalted intelligences, who, of course, possess the most extensive views of the works and providential arrangements of God, are represented as also the most humble in their deportment, and as displaying the most profound reverence in their incessant adorations. They "*fall down* before Him who sits upon the throne; and *cast their crowns before the throne*, saying, Thou art worthy, O Lord, to receive glory, and honor, and power; for thou hast created all things, and for thy pleasure they are and were created."—Their moral conduct evinces the same lowly temper of mind. They wait around the throne, in the attitude of motion, and wings outspread, ready to fly, on the first signal of their Sovereign's will; they "do his commandments, hearkening to the voice of his word," and do not disdain to perform important services, in our wretched world, to the meanest human being who is numbered among "the heirs of salvation." In like manner, were *we* indued with the grasp of intellect, the capacious minds, the extensive knowledge, and the moral powers which they possess, we would also display the same humble and reverential spirit, and feel ashamed of those emotions of vanity and pride, which dispose so many of the human family to look down with contempt on their fellow-mortals.

If the leading train of sentiment which pervades this volume be admitted, the following

GENERAL CONCLUSIONS may be deduced:—That, in conducting the religious instruction of the young, the works of God in the material world, and the most striking discoveries which have been made as to their magnitude, variety, and mechanism, should be frequently exhibited to their view, *in minute detail;* as illustrations of the attributes of the Deity, and of those descriptions of his nature and operations contained in the Volume of Inspiration;—that the books put into their hands should contain, among other subjects, popular and striking descriptions of the facts and appearances of nature;—that seminaries should be established for the occasional instruction of young persons, from the age of fifteen to the age of twenty or thirty, or upward, in all those popular branches of natural and moral science which have a tendency to enlarge the capacity of their minds, and to expand their conceptions of the incessant agency of God;—and that the Ministers of Religion, in their public instructions, should frequently blend their discussions of divine topics with illustrations derived from the scenes of Creation and Providence.

APPENDIX:

CONTAINING

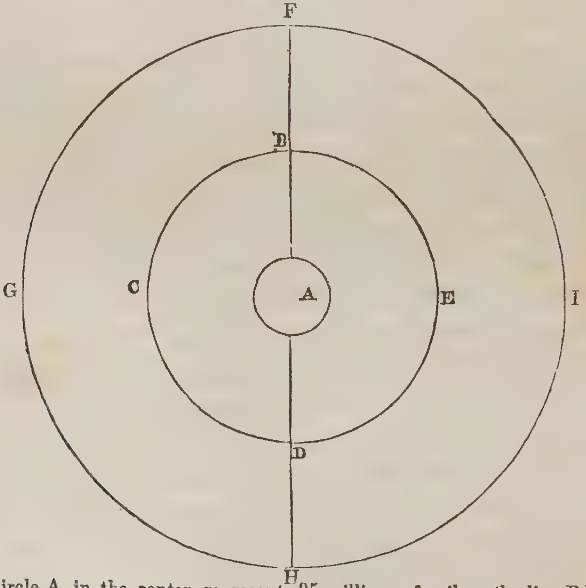
NOTES AND ILLUSTRATIONS.

NOTE I, p. 22.—*Illustration of the rate of Motion in the Heavenly Bodies, on the supposition that the earth is at rest.*

THE distance of the sun is about 95 millions of miles; consequently, the diameter of the circle he would describe around the earth would be 190 millions, and its circumference 597,142,857, which forms the extent of the circuit through which he would move in 24 hours, if the earth were at rest. This number, divided by 24, gives 24,880,952, the number of miles he would move in an hour; and this last number divided by 60, gives 414,682, the number of miles he would move in a minute. The nearest star is reckoned to be at least 20,000,000,000,000, or twenty billions of miles distant from the earth; consequently, its daily circuit round our globe would measure more than 125,000,000,000,000 miles. This sum, divided by 86,400, the number of seconds in a day, would give, 1,454,861,111, or somewhat more than one thousand four hundred millions of miles, for its rate of motion in a second of time,—a motion, which, were it actually existing, would, in all probability, shatter the universe to atoms.

The unlearned reader may, perhaps, acquire a more distinct idea of this explanation in the following figure:—

Fig. 32.



Let the small circle A, in the center, represent the Earth, and the circle B C D E the orbit of the Sun, on the supposition that he moves round the earth every 24 hours. The line A B will represent the distance of the Sun from the Earth, or 95 millions of miles; the line B D the *diameter of* the orbit he would describe; and the circle B C D E the circumference along which he would move every day, or 597 millions of miles, which is somewhat more than three times the diameter

If the line A F represent the distance of the nearest star, the circle F G H I will represent the circuit through which it would move every 24 hours, if the earth were at rest. It is obvious from the figure that since the stars are at a greater distance from the earth than the sun, the circle they would describe around the earth would be larger in proportion, and, consequently, their velocities would be proportionably more rapid; since they would move through their larger circles in the same time in which the sun moved through his narrower sphere. But, the supposition that the earth is the center of all the celestial motions, and that the different stars are daily moving around it with different velocities, and the slowest of these motions so inconceivably rapid, is so wild and extravagant, that it appears altogether inconsistent with the harmony of the universe, with the wisdom and intelligence of the Deity, and with all the other arrangements he has made in the system of nature.

NOTE II, pp. 31–94.—*Experimental Illustrations of the Pressure and Compressibility of the Atmosphere—The Diving-Bell, etc.*

The pressure of the atmosphere is most strikingly illustrated by means of the air-pump. But as few persons, comparatively, possess this instrument, the following experiments, which any person may perform at pleasure, are sufficiently convincing on this point. Take a common wine-glass, fill it with water; apply a piece of paper over the mouth of the glass; press the paper to the rim of the glass with the palm of the hand; turn the glass upside down; withdraw the hand from the paper; and the water will be supported by the pressure of the atmosphere. That it is the atmospherical pressure, and not the paper, which supports the water, is evident; for the paper, instead of being pressed down by the weight of the water, is pressed upward by the pressure of the atmosphere, and appears *concave*, or hollow in the middle. If the flame of a candle be applied to the paper, it may be held for an indefinite length of time, close to the paper, without setting fire to it. The same fact is proved by the following experiment:—Take a glass tube, of any length, and of a narrow bore; put one end of it in a basin of water; apply the mouth to the other end, and draw out the air by suction; the water will immediately rise toward the top of the tube; and if the finger or thumb be applied to the top of the tube, to prevent the admission of air, and the tube removed from the basin of water, the water in the tube will be supported by the pressure of the atmosphere on the lower end. Again:—Take a wine-glass, and burn a small bit of paper in it; and while the paper is burning, press the palm of the hand upon the mouth of the glass, and it will adhere to the hand with considerable force. In this case the pressure of the atmosphere will be *sensibly* felt; for it will sometimes require a considerable force to detach the glass from the hand.

The following experiment will also illustrate the pressure of the atmosphere. Take a tin vessel about 6 or 7 inches long and 3 in diameter, with its mouth about a quarter of an inch wide, as E F in Fig. 1.[*] Pierce a number of small holes in its bottom, about the diameter of a common sewing needle. Plunge the vessel in water; and when full, cork it up, so that no air can enter at top. While it remains corked no water will run out, being prevented by the atmospheric pressure, but the moment it is uncorked, the water will issue from the small holes in the bottom by the pressure of air from above.—The same experiment may be made by taking a tube, G H, Fig. 3,[*] 7 or 8 inches long, and about three-fourths of an inch diameter, having a small hole on each side, I K. When filled with water and corked no water will run out, but when the cork is removed the water will run out at I and K, illustrating the *lateral* pressure of the atmosphere.

The pressure of the atmosphere explains a variety of common phenomena. When we take a draught of water out of a basin or a running stream, we immerse our mouths in the water, and make a vacuum by drawing in the air; the pressure of the atmosphere upon the external surface of the water then forces it into the mouth. The same cause explains the process of a child sucking its mother's breasts—the action of a boy's sucker in lifting large stones—the rise of water in pumps—the effects produced by *cements*—the firm adhesion of snails and periwinkles to rocks and stones—the scarcity of water in the time of hard frosts—and the fact, that a cask will not run by the cock, unless a hole be opened in some other part of the cask.

The following experiment illustrates the *compressibility* of air, and at the same time the principle on which the *Diving-Bell* is constructed. Let A B, Fig. 1,[†] represent a large tumbler, nearly filled with water. Place a piece of cork on the surface of the water, and over the cork an ale-glass, C D, with its mouth downward: then push the glass perpendicularly down toward the bottom of the tumbler, and the cork will appear swimming a little above the bottom—indicating that there is no water above it in the ale-glass, but only *air*, which prevents the entrance of the water. If the water in the tumbler be supposed to represent the water of a river or of the sea, the ale-glass will represent the diving-bell in which a person may sit with safety in the depths of the sea without being immersed in the water, provided fresh air be supplied. A small quantity of water will be found to have entered the ale-glass, and the deeper it is plunged in any vessel the higher will the water rise within it; which proves the *compressibility* of the air within the glass.

The diving-bell has been much used of late in recovering valuable articles from the wrecks of ships that had sunk in deep water, and in blowing up such wrecks as are sunk near the mouths of rivers, and form impediments to navigation—by means of powder ignited by the electric spark. Major General Pasley has been employed for a considerable time past in blowing up the wreck of the Royal George man-of-war, which foundered at Spithead, near Portsmouth, in 1783. Many of the valuable articles belonging to this largest vessel of the British navy have thus been recovered. Five or six divers have been constantly employed, and no serious accidents have occurred. On the 20th June, 1842, 3065 cubic feet, or 61 loads of timber had been brought up from the wreck, beside 219 pigs of iron ballast, weighing 32 tons, 17 cwts. One of the best divers sent up 19 pigs or nearly 3 tons in one day. Most of the iron and brass cannons have thus been got up; and during the first 6 or 7 months of 1842 more than four thousand pounds of powder have been expended in these operations.—Dr. Payerne has lately invented a method for producing pure air, in such experiments, fit for the respiration of man, and for supporting flame without communication with the external air, which he has frequently successfully exhibited in London, in the diving-bell of the Polytechnic Institution; and on the 2d September, 1842, he put his invention to the test by descending at Spithead, along with Major Pasley, to the depth of 75 feet, when the water stood only 6 inches high at the bottom of the bell. The air they breathed in the bell was perfectly good; and the whole apparatus for purifying it was contained in a case not larger than a common portable writing-desk, which requires only the turning of a small winch occasionally, and no science on the part of the person in charge. When the diving-bell is once filled with compressed air, either by letting it escape from vessels previously filled with it, or by four men pumping for less than half-an-hour, no more pumping is necessary, as the air in the bell never requires to be changed. In the common mode of working the diving-bell, on the contrary, a powerful pump, manned by 6 or 8 men, would be required, as at Spithead, which must be kept constantly at work the whole time that the men are down in the diving-bell; and this incessant pumping is so laborious, that from 12 to 16 men, working in two reliefs, are necessary for the purpose of expelling the water.—Such inventions as that now stated may be applied to many practical and beneficial purposes, and perhaps to purposes more diversified and extensive than we can, in the meantime, anticipate.

---

NOTE III.—*On the ideas of Magnitude, Motion, and Duration, as expressed by numbers.* See p. 39, 41, etc.

In the pages referred to and in other parts of this work some very large numbers are expressed in *figures*. Some readers have insinuated, that it would have been better to express such numbers in *words*. The author, however, is of a different opinion; because, to some readers, not much acquainted with *Numeration*, a thousand *trillions* would convey nearly the same idea as a thousand *nonillions*, though the one number contains 58 places of figures, and the other only 22. It is chiefly the number of figures, or ciphers, in such large sums, that leads us to form a comparative estimate of their value or extent. Our ideas of magnitude and extension, conveyed by such numbers, must, of course, be very vague and undefined If we have been accustomed to traveling we have a tolerably clear conception of a *hundred*, and even of a *thousand* miles; but we have no clear nor adequate conception of a body, or of a portion of space, ten hundred thousand, ten hundred millions, or ten hundred billions of miles in extent. The mind, however, may be assisted in its conceptions, and in its comparative estimate of different numbers, by fixing on some particular number as a standard. If, according to the common reckoning, we suppose, that 5828 years have elapsed since the commencement of time, the numbers of seconds, or moments, in this period, will amount to 183,913,782,212, or one hundred and eighty-three thousand, nine hundred and thirteen millions, seven hundred and eighty-two thousand, two hundred and twelve, which is less than a fifth part of a billion. If the distance of the nearest stars from the earth be at least 20 billions of miles, then this distance may be otherwise expressed, by saying, that the number of miles which intervene between us and these bodies is more than a *hundred times greater* than the number of moments which have elapsed since the creation; and, by a similar comparison, it will be found, that the number of cubical miles, within the limits of the planetary system, is 132,000,000,000,000,000, or, one hundred and thirty-two thousand billions of times greater than the number of moments in 5828 years.

It has been computed, that the earth, supposing it a solid globe, contains about 30,000,000,000,000,000,000,000,000,000, or thirty quintillions of grains of sand, supposing a hundred grains of sand to be equal in length to an inch, and, consequently, a million of such grains for every cubical inch. If we use this number as a standard for estimating the number of *cubical* miles contained within the space which intervenes between us and the nearest stars, we shall find that the number of *cubical miles* comprehended within this space is more than ten thousand millions of times greater than the number of the grains of sand contained in the globe on which we dwell.

Though the human mind can form no definite conceptions of such numbers and magnitudes, yet it may be useful occasionally to ruminate on such subjects; as it is the only, or at least the principal mode by which limited minds like ours can approximate to an idea of the *infinity* of the Creator. And if an *image* of infinity is presented to the mind in the spaces comprehended within the limits of our system, how overpowering the conception of innumerable systems, to which ours bears no more proportion than a drop of water to the mighty ocean! How ineffably glorious must be the attributes of that Incomprehensible Being who pervades every part of this vast universe, and who continually superintends all its minute and diversified movements!

NOTE IV, p. 58.—*On the means by which it may probably be ascertained whether the Moon be a habitable world.*

About the year 1818, the Author published in the Monthly Magazine, a few observations on the surface of the Moon, in which a few remarks were offered on this subject. The following is an extract from that communication:—

"If we be ever to obtain an ocular demonstration of the habitability of any of the celestial orbs, the Moon is the only one where we can expect to trace, by our telescopes, indications of the agency of sentient or intelligent beings; and I am pretty much convinced, that a long-continued series of observations on this planet, by a number of individuals in different places, might completely set at rest the question, 'Whether the Moon be a habitable world.' Were a vast number of persons, in different parts of the world, to devote themselves to a particular survey of the Moon—were different portions of her surface allotted to different individuals, as the object of their particular research—were every mountain, hill, cavern, cliff, and plain, accurately inspected—and every change and modification in the appearance of particular spots carefully marked and represented in a series of delineations, it might lead to some certain conclusions, both as to her physical constitution, and her ultimate destination. It can be demonstrated, that a telescope which magnifies 100 times, will show a spot on the Moon's surface, whose diameter is 1223 yards; and one which magnifies 1000 times, will, of course, enable us to perceive a portion of her surface, whose size is only 122 yards; and, consequently, an object, whether natural or artificial, of no greater extent than one of our large edifices (such as St. Paul's cathedral, London), may, by such an instrument, be easily distinguished. Now, if every minute point on the lunar surface were accurately marked by numerous observers, it might be ascertained whether any changes are taking place, either from physical causes, or from the operations of intelligent agents. If a large forest were cutting down—if a city were building in an open plain, or extending its former boundaries—if a barren waste were changing into a scene of vegetation—or, if an immense concourse of animated beings were occasionally assembled on a particular spot, or shifting from one place to another—such changes would be indicated by certain modifications of shade, color, or motion; and, consequently, would furnish a direct proof of the agency of intelligent beings analogous to man, and of the Moon being a habitable globe. For although we may never be able to distinguish the *inhabitants* of the Moon (if any exist), yet if we can trace those *effects* which can flow only from the operations of intelligent agents, it would form a complete demonstration of their existence, on the same ground on which a Navigator concludes an unknown island to be inhabited, when he perceives human habitations and cultivated fields.

"That changes occasionally happen on the lunar hemisphere, next the earth, appears from the observations of Herschel and Schroeter, particularly from those of the latter. In the Transactions of the Society of Natural Philosophy at Berlin, Schroeter relates, that, on the 30th December, 1791, at five o'clock, *p. m.*, with a seven feet reflector, magnifying 161 times, he perceived the commencement of a small crater on the south-west declivity of the volcanic mountain in the *Mare Crisium*, having a shadow of at least 2″·5. On the 11th January, at twenty minutes past five, on looking at this place again, he could see neither the new crater, nor its shadow. Again, on the 4th January, 1792, he perceived, in the eastern crater of Helicon, a central mountain, of a clear gray color, 3″ in diameter, of which, during many years' observations, he had perceived no trace. 'This appearance,' he adds, 'is remarkable, as probably from the time of Hevelius, the western part of Helicon has been forming into its present shape, and Nature seems, in that district, to be particularly active.'—In making such minute observations as those to which I allude, it would be proper, along with an inspection of the Moon's luminous disc, to mark the appearances of different portions of her dark hemisphere, when it is partially enlightened by the reflected light from the earth, soon after the appearance of new moon. These researches would require a *long-continued* series of the most minute observations, by numerous observers in different regions of the globe, which could be effected only by exciting, among the bulk of mankind, a general attention to such investigations. But were this object accomplished, and were numerous observations made from the tops of mountains, and in the serene sky of southern climes, where the powers of the telescope are not counteracted by dense vapors, there can be little doubt that direct proofs would be obtained, that the Moon is a habitable world; or, at least, that the question in relation to this point would be completely set at rest."

Note V.—*Remarks on the pretended discovery of a Lunar Fortification.*

The British public, not long ago, was amused by the announcement of a discovery said to have been made by Professor Frauenhofer of Munich This gentleman was said to have discovered a *fortification* in the Moon, and to have distinguished several lines of roads, supposed to be the work of the lunar inhabitants. It is scarcely necessary to say, that such announcements are obviously premature. To perceive distinctly the shape of an object in the Moon, which resembles a fortification, it is requisite, that that object be of a much larger size than our terrestrial ramparts. Beside, although an object resembling one of our fortifications were perceived on the surface of the Moon, there would be no reason to conclude, that it served the same purpose as fortifications do among us. We are so much accustomed to war in our terrestrial system, and reflect so little on its diabolical nature, that we are apt to imagine that it must form a necessary employment even in other worlds. To be assured that a fortification existed in the Moon for the same purposes as with us, would indeed be dismal tidings from another world; for it would be a necessary conclusion, from such intelligence, that the inhabitants of that globe are actuated by the same principles of depravity, ambition, and revenge, which have infected the moral atmosphere of our sublunary world. With regard to the pretended discovery of the lunar *roads*, it may not be improper to remark, that such roads behooved to be at least 400 feet broad, or ten times the breadth of ours, in order to be perceived as faint lines through a telescope which magnifies a thousand times; which is a higher power, I presume, than Frauenhofer can apply with *distinctness* to any of his telescopes. It is not at all likely that the lunar inhabitants are of such a gigantic size, or employ carriages of such an enormous bulk, as to require roads of such dimensions, since the whole surface of the Moon is only the thirteenth part of the area of our globe.

Schroeter conjectures the existence of a great city to the north of *Marius* (a spot in the Moon), and of an extensive canal toward *Hygena* (another spot), and he represents part of the spot named *Mare Imbrium*, to be as fertile as the Campania. See *Edin. Phil. Jour.*, No. 21, *for July*, 1824. Similar remarks to those now stated will apply to these conjectures of Schroeter. We are too apt to imagine, that the objects we perceive in the Moon must bear a certain resemblance to those with which we are acquainted on the Earth; whereas there is every reason to believe, from the variety we perceive in nature, that not one world resembles another, except in some of its more prominent and *general* arrangements. The moon bears a general resemblance to the Earth, in its being diversified with mountains and valleys; but the positions and arrangement of these objects in the Moon, and the scenery they exhibit, are materially different from what appears on the surface of the terraqueous globe.

Note VI, p. 89.—*On a Plurality of Worlds.*

The doctrine of a plurality of worlds is now admitted as highly probable, both by philosophers and by enlightened divines. But it has been admitted by many persons on grounds that are too general and vague, and, consequently, a *full con-*

viction of its truth is seldom produced in the mind. In different parts of the preceding volume, I have all along taken it for granted, because I consider it as susceptible of a *moral demonstration.*—The following heads of argument, were they fully illustrated, would go far to carry demonstration to the mind on this subject; namely, That there are numerous bodies in the universe of a bulk sufficient to contain myriads of intelligent beings, and to afford them enjoyment—that there appears, in the constitution of many of these bodies, a variety of arrangements evidently adapted to this end—that, in relation to the planets of our system, there are many circumstances which bear a striking resemblance to the constitution of our globe and its appendages. They have annual and diurnal motions, moons, atmospheres, mountains, and vales—that light, and heat, and color, appear to be distributed throughout the regions of immensity; and that these agents can have a relation only to the necessities and the happiness of organized intelligences—that every part of nature, so far as our observations on the surface of this globe extend, appears to exist solely for the sake of sentient beings—that this doctrine is more worthy of the Infinite Creator, and gives us a more glorious and magnificent idea of his nature, than to suppose his benevolent regards confined to the globe on which we dwell. When these and a variety of other arguments are considered, in connection with the *Wisdom* and other attributes of the Deity, they amount not only to a high degree of probability, but to something approaching to a moral demonstration. But to illustrate these arguments in minute detail, so as to make a convincing impression on the mind, would require a volume of a considerable size. The Author flatters himself he has some original thoughts on this subject, which may probably see the light, should the present work meet with public acceptance. There is no work in our language, which takes an extensive view of this subject, in connection with the attributes of Deity and the intimations contained in Divine Revelation. Fontenelle's "Plurality of Worlds," contains a number of ingenious reasonings; but he treats the subject in too light and flippant a manner, and without the least reference to a Supreme Intelligence. The celebrated Huygens, in his "*Cosmotheoros*," instead of attempting to prove the doctrine of a plurality of worlds, takes it for granted, and indulges chiefly in conjectures respecting the organical structure and faculties of their inhabitants.*

That the Scriptures are silent on this head, has been assumed by some as a presumptive argument that this doctrine was without solid foundation. I have already endeavored to show that this assumption is unfounded?† A plurality of worlds is more than once asserted in Scripture, and in numerous passages is evidently taken for granted. Celestial intelligences are represented as ascribing "glory, honor, wisdom, and power" to the King of heaven, "because he hath created all things, and because they perceive his works to be 'great and marvelous.'" But if all the great globes in the firmament were only so many frightful deserts, destitute of inhabitants, such a universe could never inspire superior intelligences with admiration of the *wisdom* of the Creator. For wisdom consists in proportioning *means* to *ends;* but, in the case supposed, there would be no proportion between the means and the end The means are indeed great and astonishing; bu no end appears to justify such a display of creating energy.—The Psalmist, when he contemplated the heavens, was so affected with the idea of the immense population of the universe, that he seems to have been almost afraid lest he should be overlooked amidst the immensity of beings that are under the superintendence of God: "When I consider thy heavens—what is man that thou art mindful of him!" There would be no propriety nor emphasis in this exclamation, if the heavenly orbs were devoid of inhabitants; for, if no intelligent beings exist beside man, and a colony of angels, it would not appear wonderful that the Creator should exercise a particular care over the one-half of his intelligent offspring. But if we conceive the universe as composed of ten thousand times ten thousand worlds peopled with myriads of intellectual beings of various orders, the sentiments of admiration implied in the passage is extremely natural and emphatic, and conveys to us an impressive idea of the Intelligence, the Beneficence, and the Condescension of the Founder and Governor of all worlds.

NOTE VII, p. 96.—*The Daguerreotype.*

The only deficiency in the pictures produced by means of the process discovered by Daguerre is, that they do not represent objects, in their *natural colors,* as exhibited by a convex lens in a dark chamber. It is not unlikely, however, that even this perfection may soon be attained. It has been just now (Sept. 1842) stated in the public journals, that Mr. Isenrig, a painter at Munich, has announced, that he has discovered a process by which, through the daguerreotype, he can depict all the objects in nature with the brilliancy of the colors, so as to bear comparison with the finished productions of the first artists.—If this announcement be correct, we may soon expect to have all the most interesting views of the scenery of nature and the operations of art depicted with an accuracy and a beauty, which have hitherto been unattainable by the most celebrated artists.

NOTE VIII, p. 99.—*Electro-Magnetic Machines.*

The possibility of moving small pieces of mechanism by the action of the electro-magnetic power has been known for some time past, but it seems never to have been practically applied on a large scale until in 1837 it was adapted to the propulsion of a boat on the river Neva, by Professor Jacobi of Petersburg. On the 25th September, 1838, a galley, 28 feet in length and 7¼ in breadth, was provided with paddles similar to those of a steam vessel. The action was produced from 320 pair of plates, arranged along the sides of the galley, room being left for twelve persons. The vessel was made to proceed against the stream, and the speed attained in still water was three English miles per hour. The plan consisted in rapidly reversing the poles during the action. —Since the above period a machine has been contrived by Mr. R. Davidson of Aberdeen, in which a reiterated series of attractions are employed to produce the effect. The following is a brief account of Mr. Davidson's experiments, abridged from a letter of Professor Forbes of King's College, Aberdeen. Mr. R. Davidson has made an arrangement by which, with only two electro-magnets, and less than one square foot of zinc surface (the negative metal being copper) a lathe is driven with such velocity, as to be capable of turning small articles. He has another arrangement by which, with the same small extent of galvanic power, a small carriage is driven, on which two persons are carried along a very coarse wooden floor of a room. He has likewise a third arrangement not yet completed, by which, from the imperfect experiments he has made, he expects to gain very considerably more force from the same extent of galvanic power than from either of the other two. The first two machines are exceedingly simple, without the least complexity, and therefore easily manageable, and not liable to derangement, and they take up very little room. As yet, the extent of power of which they are capable has not been at all ascertained, as the size of the battery employed is so trifling, and the magnets so few; but it seems probable that a very great power, in no degree inferior even to that of steam, but much more manageable, much less expensive, and occupying greatly less space—if the coals be taken into account—may be obtained. The Professor considers Mr. Davidson's inventions to be so interesting to railroad proprietors in particular, that it would be much for their interest to take up the subject and be at the expense of making the experiments necessary to bring this power into operation on a great scale.—The difference between Professor Jacobi's plan and Mr. Davidson's is this;—that Jacobi produces motion by changing the poles of the magnets, and Mr. Davidson, by cutting off the galvanic current at given points—the power of alternating as the rotation proceeds, from a neutralized magnet to a newly changed one. In both experiments it has been clearly demonstrated that the power of the magnet is increased, by increasing the diameter, and adding to the length of the helix. The power is also increased by increasing the size of the bars.

---

* Since the first editions of this work were published, the author has fully illustrated the topics above stated, along with other kindred subjects, in his volumes entitled "Celestial Scenery," and "The Sidereal Heavens," which are embellished with numerous engravings.

† See p. 89.

Note IX, p. 114.—*On the first Inventor of Printing.*

Mr. Ireland, in his "Picturesque Tour through Holland, Brabant, and part of France, in 1789," gives the following account of the Inventor of Printing, when describing the city of Haerlem.

"Haerlem claims the invention of the art of Printing. It is attributed to Lawrence Koster, an alderman of this city, in 1440; whose house is yet standing in the market-place, opposite the church. Amusing himself one day in the neighboring wood, with cutting the bark of trees into letters that formed the initials of his name, he is said to have laid them on paper, and, falling asleep, when he awoke, observed, that, from the dew their form was impressed on the paper. This accident induced him to make further experiments; he next cut his letters in wood, and, dipping them in a glutinous liquid, impressed them on paper, which he found an improvement; and, soon after, substituting leaden and pewter letters, erected a press in his house; thus laying the foundation of this noble art, which has thence gradually arisen to its present excellence.—The art, it is said, was stolen from him by his servant, John Faustus, who conveyed it to Mentz, and, from the novelty of the discovery, soon acquired the title of Doctor and Conjurer. The original specimens are now shown at the Library in the Town Hall. The first is on a leaf of parchment, and the second and third on paper, printed only on one side, and the corners left blank for capitals. At the top are wooden cuts, representing the Creation, and, as it is called, Lucifer's Fall."—pp. 109-111.

Note X, p. 117.—*On Telescopes; with a brief notice of a* New Reflecting Telescope, constructed by the Author.

It is doubtful to what particular individual we owe the invention of the telescope. Some have supposed that Roger Bacon and Baptista Porta invented this instrument. Borelli ascribes the invention to Zacharias Jansen, a native of Middleberg. Perhaps the account given in the article to which this note refers, and which is stated by a variety of authors, may be as probable as any other. It is certain the telescope was not in general use until the beginning of the 17th century, and that no discoveries in the heavens were made with it until the year 1609

There are two kinds of telescopes, *Refracting* and *Reflecting*. In refracting telescopes, the rays of light pass through convex or concave glasses or lenses. The object-glass is always convex, and forms an image or picture of the object in an inverted position in its focus, which image is viewed by the eye-glass; and the magnifying power is in the proportion of the focal distance of the object-glass to that of the eye-glass. The focal distance of a convex glass may be ascertained by holding it in the rays of the sun, opposite to a piece of white paper, and measuring the distance between the glass and the white spot, or burning point, formed on the paper. An astronomical telescope for viewing celestial objects may be constructed with only two glasses. If an object-glass, 30 inches focal distance, be fixed in the end of a tube, and an eye-glass of one inch focus be placed at the other end, at the distance of 31 inches from the object-glass, a telescope will be formed which will magnify in the proportion of one to thirty, or 30 times; that is, objects seen through such a telescope will appear thirty times larger in diameter, or thirty times nearer than to the naked eye. By such an instrument, the inequalities on the Moon's surface, and some of the satellites of Jupiter, may be perceived; but when directed to land objects, they will appear inverted or turned upside down. In order to reverse the appearance of the object, two other eye-glasses are required;—or, if a *concave* eye-glass of a similar focus be placed at 29 inches from the object-glass, the object will appear in its natural position, and the magnifying power will be the same; but the field of view will be much smaller. Astronomical telescopes of this construction were formerly made of 120, and even of 200 feet in length, and were used without a tube; the object-glass being placed on the top of a long pole; but these are now entirely superseded by *achromatic* telescopes. In the achromatic telescope, the object-glass is compounded of two, and sometimes of three lenses, placed close to each other, one of which is a double concave of white flint glass, and the other a double convex of crown glass. By this means an image is formed without being blended with the prismatic colors; and it will, therefore, bear a large aperture, and a much greater magnifying power, than a common refractor. A good achromatic telescope four feet long will magnify objects as much as a common refractor 100 feet long.

In *Reflecting* telescopes the images of objects are formed by speculums or mirrors, instead of lenses. They are of two kinds, the *Gregorian* and the *Newtonian*. The Gregorian Reflector consists of a tube in which a concave mirror, having a hole in its center, is placed. The rays of light from distant objects falling upon this mirror, form an image before it, in its center or focus. This image is intercepted by a smaller mirror, which reflects it back, through the hole in the large mirror to an eye-glass, through which the observer views the object. In the Newtonian Reflector, a plane mirror, placed at an angle of 45 degrees, is substituted in place of the small mirror, in the Gregorian construction, and the observer looks upon the object through the side of the tube. Sir David Brewster has suggested an interesting improvement in the construction of this instrument, which is described in the *Edin. Encyc.*, Art. *Optics*, p. 644.

New Reflector.—Several years ago, the Author commenced a series of experiments on Reflecting Telescopes; and has lately constructed several on a new plan and principle. In this construction there is no *small* speculum, either plane, convex, or concave; there is no tube, except a short one of two or three inches in length, for holding the speculum. The observer sits with his back to the object, and views the image formed by the speculum through an eye-piece, which requires to be nicely directed and adjusted. Three or four instruments of this construction have been fitted up, with specula of 16, 28, 35, and 49 inches focal distance. One of them, having a speculum of eight inches focus, and two inches diameter, with a terrestrial eye-piece, magnifying about 25 times, forms an excellent parlor telescope for viewing land-objects, and exhibits them in a brilliant and novel aspect. When compared with a Gregorian of the same size and magnifying power, the quantity of light upon the object appears nearly doubled, and the image is *equally distinct*. It represents objects in their natural colors, without that dingy and yellowish tinge which appears when looking through a Gregorian. Another of these instruments, having a speculum of 28 inches focal distance, and an eye-piece producing a magnifying power of about 100 times, serves as an excellent astronomical telescope. By this instrument the belts and satellites of Jupiter, the ring of Saturn, and the mountains and cavities of the Moon, may be contemplated with great ease and distinctness. By placing the pedestal on the floor of the apartment, when the object is at a high elevation, we can view celestial phenomena with the same ease as if we were sitting at a writing-desk reading a book. With a magnifying power of about 40 times applied to this telescope, terrestrial objects appear extremely bright and well defined. A speculum of 49 inches focal distance, and 6½ inches diameter, has lately been fitted up on the same principle. With magnifying powers of from 100 to 130 times, it exhibits distinct and interesting views of the Moon's surface and of the ring of Saturn, and with a power of 56 times it affords a beautiful view of land objects. The specula used in some of these instruments are far from being good; being of a yellowish color, and scarcely half polished, and having large holes in the center; as they were originally intended for Gregorian reflectors; yet the brightness of vision approaches nearly to that of Achromatic Telescopes. The experiments which have been made on this subject demonstrate, that a *tube* is not necessary for a reflecting Telescope, when viewing either celestial or terrestrial objects; and, therefore, this construction of the instrument may be denominated, The Aerial Reflector. The simplicity of the construction, and the excellence of the performance of these instruments, have been much admired by several scientific gentlemen to whom they have been exhibited.[*]

In the system of Optics, lately published in the Edinburgh Encyclopedia (one of the most luminous and comprehensive treatises which has yet appeared on this subject), the writer in his introduction to the account of Sir D. Brewster's improvement on the Newtonian Telescope, remarks: —"If we could dispense with the use of the small specula in telescopes of modern length, by inclining the great speculum, and using an oblique, and consequently a *distorted* reflection, as proposed first by La Maire, we should consider the Newtonian Telescope as perfect, and, on a large scale, or when the instrument exceeds 20 feet, it has undoubtedly this character, as nothing can be more simple than to magnify, by a single eye-glass, the image formed by a single speculum.—As the *front view* is quite *impracticable*, and, indeed, *has never been attempted* in instruments of a small size, it becomes of great practical consequence to remove as much as possible the evils which arise from the use of a small speculum," etc. The instruments noticed above have effectuated the desirable object alluded to by this respectable writer; and the principle of the construction is neither that of Sir W. Herschel's *front view*, nor does it coincide with that proposed by La Maire, which seems to have been a mere hint, which was never put into execution.

Note XI, p. 119.—*On Steam Navigation, etc.*

The application of steam, as a mechanical power, for impelling vessels and carriages, is one of the most brilliant and useful achievements of art which distinguish the present age, and is rapidly producing an important and interesting change both on inland and foreign intercourse. The fact that a vessel can be impelled by steam, against wind and tide, at the rate of twelve miles an hour, and a carriage on a railway with a velocity of thirty and upward, is sufficient to account for such a change. From the "Report of a Committee of Parliament," published in 1822, it appears, that the first application of steam to the impelling of vessels was made by an Englishman of the name of Hull, who, in 1736, obtained a patent for the invention of a steamboat, to be moved with a crank and paddles. But it was only in 1807 that the invention was fairly brought into practical use by Mr. Fulton, who had the advice and assistance of Mr. Bell, a Scottish engineer. In Britain, the first successful application of steam to vessels was made by Mr. Bell,[†] who built the Comet, of 25 tons and 4 horse power, to ply on the Clyde. Glasgow, which had the honor of introducing steam navigation on this side of the Atlantic, is still the seat of its greatest activity. In 1840, there were no less than 76 steamers of various sizes, comprising nearly 8000 tons, plying on the Clyde. Some of these, beside performing regular voyages to Inverary, Cambelton, Belfast, Dublin, Londonderry, Cork, Bristol, Liverpool, and other places, are also performing tours, during the summer months, to the Giant's Causeway, Staffa, Skye, and other parts of the Western Isles, and to Inverness by the Caledonian canal. Steam-vessels are also plying between Inverness and London, Perth and Dundee, Dumfries and Liverpool, Aberdeen and Leith, Dundee and London, Aberdeen and London, Leith and Dundee, Leith and London, Dover and Calais—from Liverpool to Lisbon, Cadiz, Gibraltar, Malaga, etc. In 1840, there were throughout Great Britain and its colonies, no less than 630 steam-vessels, possessing an aggregate burden of 71,000 tons. The rivers on which these vessels chiefly ply are the Thames, the Severn, the Mersey, the Tyne, the Tay, the Forth, and the Clyde. From the Thames steamers proceed to Rotterdam, Boulogne, Havre, and many other ports on the continent. From Liverpool steam-vessels now regularly sail to the West Indies and America. These vessels are of an enormous size. The *Great Western*, the first steamer that sailed to America, is 1340 tons burden. The *Victoria* is a vessel of 500 horse power, and 27 feet longer than our largest man-of-war. The *British Queen* measures in entire length 275 feet. Her two engines are of 250 horse power each, and she is calculated to carry 1862 tons. Her outward voyage of 18 days requires a consumption of 540 tons of coal, and her homeward voyage of 12 days 360 tons. But larger vessels than even these are now in preparation. A regular communication is also now established by steam between Britain and India, by the Mediterranean, Egypt, and the Red sea.

---

[*] The reader will find a more particular account of these instruments, accompanied with engravings, in the Edinburgh Philosophical Journal for July, 1826; the "London Encyclopedia," Art. *Telescope*, and in the "London Mechanics' Magazine" for August, 1826. The Author has given a more particular description of these and various other astronomical instruments, in a work recently published.

[†] It is much to be regretted, and is certainly not congenial to the generous spirit of the age, that this gentleman, who was among the first inventors of steam navigation, and who did so much to promote its success in the neighborhood of Glasgow, never received any public reward for his services, but was allowed to finish his days in a condition approaching to poverty.

Steam navigation on the continent is likewise making rapid progress. Steam-vessels are now to be found on the Garonne, Seine, Danube, Rhine, Rhone, lakes of Geneva and Constance, etc. It is likely that, in the course of a few years, such conveyances will be established on most of the friths and rivers both in Europe and America: and the period is no doubt hastening on when voyages will be made in such vehicles to the most distant regions of the world. A steam-vessel has for many years been sailing regularly, summer and winter, between New York and New Orleans, a distance of 2000 miles, in an open sea, exposed to great storms. On the coasts and rivers of North America, steam navigation is carried on to a much greater extent than in Great Britain or any other country. There are about 500 steam-vessels, most of them of very large size, plying on the Ohio, Mississippi, and other western waters. In this country, steam-vessels are fitted up with every accommodation and elegance which art can devise; so as to produce, if possible, as great a variety of enjoyment to passengers on sea as on land. Mr. Church, the American consul in France, in 1822, invented a paddle that revolves on the paddle-wheel by a very simple mechanism, which is found to save power. In the United States, a new mode of constructing cabins has been introduced, so as to place them beyond the reach of injury from explosions of the boiler. “The American steam-vessels are larger than ours, and are much more used for the conveyance of merchandise. The average proportion is about 1 horse power for every 4 tons of burden, computed in the usual way. The velocity is found to be nearly as the square of the power, so that an 80 horse power engine will produce only *twice* the velocity of one of 20 horse power. Something depends also on the make and size of the vessel. Several years ago, the *Sovereign*, of 210 tons and 80 horse power, went $9\frac{3}{4}$ miles an hour in still water; and the *James Watt*, of 448 tons, and 100 horse power, 10 miles. For the paddle-boards, the rule is, that 3-10ths of a square foot of surface be immersed in the water for each horse power. Mr. Gladstone affirms, that so much power is wasted in displacing the water by the stroke of the board, that the velocity of the ship is only about one-half of that of the outer surface of the paddle-wheel. There are two sources of apprehension in steam-vessels—fire and the bursting of the boiler. With regard to the latter, when the boiler is of low pressure, it is satisfactorily established that not the smallest danger exists. And in the best constructed vessels, the danger from fire is completely obviated, by separating the furnace from the sides of the vessel by five inches of water.”

An interesting Report was published some years ago of a series of experiments, made with *a new steam engine*, invented by an American machinist, called the *capillary steam engine.* Three great objects are said to be accomplished by this invention—*lightness, safety and economy of fuel.* In an engine calculated for a 4 horse power, the *generator* is formed of a copper tube, $\frac{1}{4}$ of an inch in diameter, and 100 feet long, which weighs about 16 lbs. It is arranged in coils, one above another, in the form of a sugar loaf, 30 inches high; the bottom coil being 18 inches in diameter, and the top one considerably less. The wood is prepared as is usual for a stove, and put within the coils.—The *steam cylinder* is formed of sheet copper, 3 inches in diameter, 27 inches in stroke, and, with all its appendages, weighs about 25 lbs. It has been ascertained that the generator and main cylinder, with their contents and appendages, exclusive of fuel, need not weigh more than 20 lbs. to the horse power. *No harm can be done by the bursting of boilers*—even a safety-valve is considered as useless. In the course of the experiments, the experimenters several times burst the tube; but so far from doing any injury, it could not always be perceived by the spectators.

To ascertain what may be done toward *aerial navigation* by steam, experiments were made on the power of wings in the air, and on the power necessary to work them. The result is, that it requires a horse power to every 30 lbs. in the air; so that a flying engine, to be worked by charcoal, would weigh about 30 lbs. to the horse power, wings, condenser, and fuel included. It was also ascertained by experiments and calculations, that a balloon could be made to carry a man with an engine, which would push it at the rate of 15 miles an hour in the air. A more particular detail of these experiments may be seen in the London Mech. Mag., No. 60, for 16th Oct. 1824.

“What steam is doing to facilitate intercourse by water, it is also doing on land. By means of the iron-railway, the speed of traveling in steam-carriages is treble that which is attainable by horses. The railway course is level; to accomplish which the same obstacles have to be overcome in its construction that are met with in making a canal — the high ground to be cut through and bridges to be thrown over the low. Since the railway for steam-carriages between Liverpool and Manchester was opened, a few years ago, the country has been getting intersected by others in every direction. Between these two towns, the number of passengers by this mode of conveyance averaged in 1831 about 1300 daily.—To transport all these by four-horse coaches, each allowed to carry 20 individuals, and to travel

60 miles per day, and each horse to run 20 miles, would require upward of 32 of such coaches and 390 horses. Traveling by steam is also making rapid progress on the continent and in America. Between Paris and St. Germain a substantial railway has been lately opened, with 105 vehicles, for passengers only, capable of containing 4070 persons, and of transporting the whole population of Paris to St. Germain in one day. This railway traverses no fewer than eighteen bridges, three of which are across the Seine. The rails are fifteen times heavier than those between Liverpool and Manchester. Steam-carriages have repeatedly been constructed to run on common roads; but the friction there is so great, except where the ground is very smooth, hard, and level, that, with other impediments, they have not been found to run to advantage."

Among the numerous purposes to which steam is now applied is that of breaking stones for the construction of roads. The stones are put into a kind of hopper above, and pushed down with a rake, and the machine is worked by a rotatory motion of one horse power; and will break a ton of hard pebbles, completely, in from six to eight minutes. A steam machine has also been invented for the dressing of woolen cloth, which does as much work in 50 minutes as two men could do in two days.—*Mon. Mag. Aug.* 1823, p. 71.

NOTE XII, p. 146.—*Strictures on a certain sentiment respecting the Work of Human Redemption.*

The sentiment referred to in this paragraph, "That there never was nor ever will be, through all the ages of eternity, so wonderful a display of the Divine glory as in the cross of Christ," has been frequently reiterated, in sermons and in systems of divinity, and is still repeated by certain preachers as if it were an incontrovertible axiom, which ought never to be called in question; and is no doubt intended to magnify the Divine attributes and the work of redemption. But it is nothing more than a presumptuous assumption, which has a tendency to *limit* the perfections of Deity, and to present a partial and distorted view of the economy of human redemption. For, in the first place, *it has no foundation in Scripture.*—There is not a single passage from which it can be legitimately deduced. The *onus probandi*, on this point, rests with those who make the assertion. A gentleman, when lately conversing on this subject, brought forward the following interrogation, as a demonstrative argument in proof of the position in question: "Is not redemption declared in Scripture to be *the chief of all the works of God?*" but he was not a little surprised when he was informed that the passage, which he had partly misquoted, is applied to the behemoth, or the elephant, as stated in Job, xl, 19.—2dly, The assertion is as presumptuous as it is unfounded. It takes for granted that we know all the events which have already happened, and which are now taking place throughout the whole range of God's universal empire. This empire seems unbounded; and that portion of it which we can minutely explore is but as a point in comparison of the whole. But before we can, on good grounds, hazard such an assertion as that under consideration, we must have explored *all* the dispensations of God, through every portion of his vast dominions; and be able to form a comparison between the different displays of divine glory made to all the different classes of intellectual beings under the government of the Creator. And who among the sons of Adam can lay claim to such high qualifications for pronouncing so sweeping a decision on this point?—3dly, *It sets limits to the Divine perfections and operations.* For although it could be proved (which it cannot be), that no such display have hitherto been made to any other beings, yet who can take upon him to assert that displays of Divine perfections, far more glorious and astonishing, will not be exhibited during countless ages of eternity which are yet to come? To set limits to the operations of Almighty power and boundless benevolence, during the lapse of infinite duration, is not the province of any created intelligence, and far less of man, who stands so low in the scale of universal being.—4thly, *It tends to damp the hopes and prospects of immortal beings,* when looking forward to an interminable existence. For this sentiment leads them to conclude that they are already acquainted with the greatest display of Divine glory which can be made; and that, whatever scenes of wonder may be exhibited in the future world, they must of course be all inferior to this in point of extent and grandeur.

The redemption of the human race, as displayed in the Christian revelation, is a theme sufficiently grand, astonishing, and interesting to command the attention of all who are convinced that they belong to an apostate race of intelligences, and to excite the admiration and gratitude of all who have experienced its benefits; and it stands in no need of such unfounded and extravagant assertions to display its riches and glory. "Will a man speak deceitfully for God! Shall not his excellency make you afraid, and his dread fall upon you?" We pronounce nothing decisively on this subject. We feel ourselves chained down to an obscure corner of God's dominions—to be in the very infancy of our knowledge, and withal to be connected with a race of beings whose "understandings are darkened by reason of sin;" and are, therefore, unable to pronounce an infallible decision on what God will or will not do. Were we to hazard a conjecture on this subject, we would say that the converse of the proposition under consideration is more probable than the proposition itself. We can conceive worlds ten thousand times more populous than ours, and peopled with a higher order of intellectual beings, toward whom a similar display of benevolence and mercy, were it necessary, may be made; and, therefore, in point of *the extent* of its objects, we can conceive the love of God more illustriously manifested than even to the inhabitants of our globe. But whether such an event shall ever take place, it would be presumption in us to determine. For the thoughts and the ways of God as far transcend ours "as the heavens are high above the earth." It demands our highest tribute of grateful adoration, that the Almighty condescended to "regard us in our low estate," and to deliver us from the moral degradation into which we had fallen; but surely it would be unreasonable to conclude, from this consideration, that of all the rational tribes which people the universe, MAN is the only favorite of the Most High, "when thousand worlds are round." Though myriads of other intelligences were to share in similar favors, it would not lessen the happiness conferred on us, nor ought it in the least to detract from our admiration of "the love of God which is in Christ Jesus our Lord."

There are a great many other vague and untenable notions which are entertained and reiterated by certain commentators and divines, as indisputable axioms, which it would be of importance to the cause of religion to discard; such as, that angels are pure *immaterial* substances—that they were formed on the first day of the Mosaic creation—that the *wisdom* of God is nowhere so illustriously displayed throughout the universe as in the scheme of redemption—that the chief employment of the future world will be to pry into the *mysteries* of salvation—that sin is an *infinite* evil—that the whole material universe was brought into existence *at the same time* with our earth—that the Creator ceased to create any new order of beings in the universe after arranging the fabric of our globe—that the whole system of material nature in heaven and earth will be destroyed at the period of the dissolution of our world—that our thoughts and affections should be completely detached from all *created* things, etc. Several vague notions of this description are founded on the false assumption, that the globe we inhabit and the rational beings that have appeared on its surface from age to age, are the *chief objects* of God's superintendence and care—and that the Scriptures are *the only medium* through which we can view the plans and operations of the Deity—assumptions which are contrary to reason, which are unwarranted in Revelation, nay, which are directly contradicted in numerous passages of Scripture, some of which have already been referred to in the course of this volume. It would be of essential service to the cause of Christianity, that its doctrines, facts, and moral requisitions were uniformly exhibited in their native simplicity and grandeur, without being obscured and distorted by the vague and extravagant representations with which they are too frequently blended by injudicious minds.

NOTE XIII.—*Extracts from Dr Dwight's Theology.*

As authority has a considerable degree of weight on some minds, I shall conclude with an extract on the subject of this volume, from that respectable and enlightened divine, Dr. Dwight, late President of Yale College:—"The works of God were by him intended to be, and are, in fact, manifestations of himself; proofs of his character, presence, and agency. In this light he requires men continually to regard them; and to refuse this regard is considered by him as grossly wicked, and highly deserving of punishment. Psalm xxviii, 5; Isaiah, v, 12–14. I am apprehensive that even good men are prone to pay less attention to the works of creation and providence than piety demands and the Scriptures require. We say and hear so much concerning the insufficiency of these works to unfold the character of God and the nature of genuine religion, that we are prone to consider them as almost uninstructive in moral things, and in a great measure useless to the promotion of piety. This, however, is a palpable and dangerous error. The works *alone*, without the aid of the Scriptures, would, I acknowledge, be far less instructive than they now are, and utterly insufficient to guide us in the way of righteousness. The Scriptures were designed to be a comment on these works; to explain their nature, and to show us the agency, purposes, wisdom, and goodness of God in their formation. Thus explained, thus illuminated, they become means of knowledge, very extensive and eminently useful. He who does not find in the various, beautiful, sublime, awful, and astonishing objects presented to us in creation and providence, irresistible and glorious reasons for admiring, adoring, loving, and praising his Creator, has not a claim to evangelical piety."—*System of Theology*, vol. iii, p. 477.

NOTE XIV.—*List of Popular Works on the different Sciences treated of in this volume, with occasional Remarks.*

SELECT BOOKS ON NATURAL HISTORY.

Goldsmith's History of the Earth and Animated Nature—with numerous notes from the works of the most distinguished British and foreign naturalists, embodying the most recent discoveries in natural history—illustrated by nearly 2000 figures, in 2 vols., royal 8vo., edited by Mr. Whitelaw, and published by Blackie & Son.—This edition of Goldsmith is unquestionably the most complete that has yet appeared. It contains nearly double the quantity of matter in the original work, and an account of the latest discoveries down to the period of its publication in 1840.—The Gallery of Nature and Art, by Dr. Mason Good and others, 6 vols., 8vo.—*Spectacle de la Nature,* or Nature Displayed, 7 vols., 12mo.—Nature Displayed, by Dr. Simeon Shaw, 3 vols., 8vo., or in 6 vols., 12mo. This work, though chiefly a compilation, embodies a great variety of interesting and popular descriptions of the most remarkable facts in the system of nature, which are illustrated with numerous engravings, both plain and colored. Clarke's Hundred Wonders of the World, 1 vol., 12mo., and Platt's Book of Curiosities, contain a number of interesting selections on this subject.—Smellie's Philosophy of Natural History, 2 vols., 4to., and his translation of Buffon's Natural History.—Bingley's Animal Biography, 4 vols., 8vo.—Works entitled "Systems" and "Elements" of "Natural History," are numerous; but the greater part of them is confined to descriptions of the forms, habits, and instincts of animals. On this department of natural science, a work was published some time ago by the celebrated Cuvier, entitled *The Animal Kingdom,* with engravings chiefly from the living subjects in the museum of natural history at Paris.—A work on the same subject has been publishing for several years past, in 12mo. vols., entitled *The Naturalist's Library,* by Sir W Jardine. Every volume contains about 34 plates, with the figures colored from nature, along with a biographical sketch, and a portrait of some eminent naturalist or philosopher. About 40 vols. have already been published, price 6s. each.—A Popular and Comprehensive History of the facts which have been ascertained respecting the earth, the atmosphere, the meteors, the heavens, etc., calculated for general readers, and interspersed with appropriate moral and religious reflections, is still a *desideratum.* The facts of natural history, next to the facts recorded in the sacred volume, are the first subjects to which the minds of the young should be directed in the course of a general education.

SELECT BOOKS ON GEOGRAPHY.

Pinkerton's Modern Geography, 2 vols., 4to., and the Abridgment, 1 vol., 8vo.—The Glasgow Geography, in 5 vols., 8vo. This work comprehends an immense mass of information on the historical and descriptive parts of geography. It also contains comprehensive compends of astronomy, geology, meteorology, etc.—Malte Brun's

System of Geography, 7 vols., 8vo. The English translation of this work contains the fullest and most comprehensive view of universal geography that has yet appeared in our language, including details of the most recent discoveries. The first volume contains a luminous and comprehensive outline of the science of geology and physical and mathematical geography.—Murray's Encyclopedia of Geography, 1 vol., 8vo. This work contains a great mass of information on the subjects connected with geography, and numerous engravings.—Woodbridge's System of Universal Geography, with maps and numerous engravings.—Bell's Geography.—Myer's System of Modern Geography, with maps, views, engravings representing costumes, etc., 2 large vols., 4to.—Cooke's System of Universal Geography, in 2 very large 4to. volumes, closely printed, contains a great variety of interesting sketches in relation to *descriptive* geography, extracted from the writings of modern voyagers and travelers; the details of incidents, etc., being related, for the most part, in the words of the respective authors from whom the information is collected.—Winterbotham's Geographical and Historical View of the United States of America, etc., 4 vols., 8vo.—Morse's American Geography, 8vo.—Goldsmith's Geography on a popular plan, contains an interesting account of the manners and customs of nations, for the entertainment and instruction of the young, illustrated with above 60 engravings. Of smaller systems, there is a great abundance in the English language; but most of them are extremely deficient, particularly in what relates to *general* geography.—On *sacred* geography, Well's Geography, modernized by the Editor of Calmet's Dictionary, is the most complete work of its kind. On *physical* or *general* geography: Playfair's System of Geography, vol. I, and Varenius's General Geography. A MODERN *system* of general geography, in a separate form, on the plan of Varenius, is a *desideratum*.—Edin. Encyc., Art. *Geography*.—Encyc. Brit., 7th edition, Art. *Physical Geography*, etc. Books of Voyages and Travels generally contain the most circumstantial details of the physical aspects of the different countries, and of the dispositions and customs of their inhabitants; and present to the view of the Christian philanthropist those facts and principles from which the *moral* state and character of the various tribes of human beings may be inferred. The following works contain comprehensive abridgments of the most celebrated voyages and travels:—Pinkerton's General Collection of Voyages and Travels in all parts of the World, 17 vols., 4to.—Mavor's Voyages, etc., 28 vols., 18mo.—The World Displayed, 18 vols., 18mo.—Phillips's Collection of Voyages and Travels, etc.—Conder's Modern Traveler, 20 vols.

The following are among the most respectable modern publications on this subject, arranged according to the different quarters of the world:—ASIA. Valencia's Travels in India, Arabia, etc.—Porter's Travels in Georgia, Armenia, etc.—Golownin's Travels in Japan.—Staunton's Account of Macartney's Embassy to China.—Raffles' Travels in Java.—Clarke's Travels in Asia Minor and the Holy Land.—Chateaubriand's Travels in Palestine.—Ali Bey's Travels in Arabia.—Sir Alexander Burness's Travels in India, etc.—Stephens' Incidents of Travel in Egypt, Arabia Petrea, and the Holy Land.—Morier's Travels through Persia.—Historical and Descriptive Account of British India, 3 vols.—Historical and Descriptive Account of China, 3 vols.—Crichton's History of Arabia.—Frazer's Account of Persia.—Russell's Palestine, etc.——AFRICA. Lyon's Travels in Northern Africa.—Burckhardt's Travels in Nubia.—Bruce's Travels in Abyssinia.—Salt's Travels in Abyssinia.—Bowditch's, Hutton's, and Dupuis's Account of Ashantee.—Park's and Lander's Travels in Africa.—Leigh's Journey in Egypt.—Belzoni's Travels in Egypt.—Sonini's Travels in Egypt.—Barrow's, Burchell's, and Campbell's Travels in Southern Africa.—Russell's Account of Nubia, Abyssinia, and the Barbary States, and View of Ancient and Modern Egypt.—Narrative of Discovery and Adventure in Africa, with Illustrations of the Geology, Mineralogy, and Zoology, etc.——AMERICA. Howison's Sketches of Upper Canada.—Stewart's Three Years in America.—Tytler's Views of the Northern Coast of America.—Humboldt's Travels in South America.—Duncan's Travels in the United States.—Miss Martineau's Society in America.—Buckingham's Travels in the United States of America.—Luccock's, Vidal's, Koster's, and Hall's Travels in South America, etc.——EUROPE. Henderson's and Mackenzie's Travels in Iceland.—Thomson's Travels in Sweden.—Carr's Travels in Russia, Denmark, etc.—Pallas's Travels in Russia.—Wraxall's, Neale's, Coxe's, and Lemaistre's Tours through France, Switzerland, Germany, etc.—Burgoing's and Jacob's Travels in Spain.—Brydone's Tour in Sicily, etc.—Von Buck's Travels in Norway and Lapland.—Cochrane's Travels in Siberia, etc.—Cooke's, Anson's, Byron's, Perouse's, and Bouganville's Voyages round the World, etc.—Prior's Universal Traveler, 1 thick vol., 12mo., closely printed, with 100 engravings.

SELECT BOOKS ON GEOLOGY.

Kirwin's Mineralogy, and his Geological Essays.—De Luc's Geology, and his Geological Travels.—Parkinson's Organic Remains of a former world, 3 vols., 4to.—The Fossils of the South Downs, or Illustrations of the Geology of Sussex, by G. Mantel, F.L.S.—The preliminary Essay to this splendid Work contains several excellent remarks respecting the connection of Geology with Religion, which are calculated to advance the interests of both.—Cuvier's Essay on the theory of the Earth, with Illustrations by Professor Jamieson, 4th edition.—Playfair's Illustrations of the Huttonian Theory of the Earth.—Transactions of the Geological and Wernerian Societies.—Dr. P. Smith's Lectures on Geology as connected with Revelation.—Dr Hitchcock's Treatise on Geology—his Connection between Geology and Natural Religion—and his Connection between Geology and the Mosaic Account of the Creation.—Lyell's Geology.—Buckland and Babbage's Bridgewater Treatises.—Macculloch's System of Geology.—Hugh Miller's Old Red Sandstone.—Buckland's Account of the discovery of a Den of Hyenas in a cavern in Yorkshire.—Buckland's Treatise on Geology, 2 vols., 8vo.—Bakewell's Introduction to Geology.—Phillips's Outlines of Mineralogy and Geology, 12mo.—This last work forms a good introduction to the study of Geology, for those who are just commencing their inquiries on this subject. The object of this science, in the meantime, should be confined chiefly to *the collecting of facts*, in reference to the structure of the earth and the changes it has undergone. The exterior aspect of our globe, and its internal recesses, must be still more extensively explored, before any theory of the earth can be established on a broad and solid foundation. It should be left to future ages to build a system with the materials we are now preparing.

POPULAR WORKS ON ASTRONOMY.

Brewster's Ferguson's Astronomy, 2 vols., 8vo., with a vol. of plates. The notes and supplementary chapters of this work, written by Sir D. Brewster, contain a full and comprehensive detail of all the modern discoveries in this science.—Bonnycastle's Introduction to Astronomy, 1 vol., 8vo.—La Place's System of the World, 2 vols., 8vo.—Dr. Olinthus Gregory's Astronomy, 1 vol., 8vo.—Mrs. Bryan's System of Astronomy, 8vo.—Adams' Astronomical and Geographical Essays, 8vo.—Phillips's Eight Familiar Lectures on Astronomy, 12mo.--Herschel's Astronomy.--Squire's Grammar of Astronomy, one thick vol. 18mo., closely printed, and illustrated with 35 plates.—Arago's Lectures on Astronomy.—The Wonders of the Heavens, 12mo.—This work contains a popular view of the principal facts of Astronomy, and is illustrated with 50 elegant engravings of a variety of interesting objects connected with the scenery of the heavens; but its discussions are too frequently blended with the peculiarities of a modern physical theory.—Martin's Gentleman and Lady's Philosophy, vol. 1.—Derham's Astro-Theology, and Whiston's Astronomical Principles of Religion, 8vo.—Baxter's Matho, 2 vols., etc.—An elegant and comprehensive outline of the leading facts of Astronomy in their relation to Revealed Religion, will be found in Dr. Chalmers's Discourses on the Christian Revelation, viewed in connection with Modern Astronomy, 8vo.—The general reader, in commencing his study of this science, will find Bonnycastle's "Introduction" a very interesting work. It is written in an elegant and animated style, and is agreeably interspersed with a number of appropriate reflections; but it is deficient in the detail of modern discoveries. He might next proceed to the perusal of Ferguson, Gregory, Squire, etc.—La Place's work contains a beautiful exposition of the Newtonian system; but it is glaringly deficient in reference to the Wisdom and Agency of a Supreme Intelligence. "An undevout astronomer is mad." Baxter's Matho contains a popular and interesting view of this subject, and forms a striking contrast to the apathy of La Place, who carefully keeps out of view the agency of the Creator —the main design of this author being to connect the phenomena of the heavens and the earth with the attributes of Deity, and the high destination of immortal minds. Though this work passed through three editions, it does not seem to have been appreciated according to its merits. As it has now become scarce, a new edition with *notes*, containing a detail of modern discoveries, might be an acceptable present to the public. Those who wish to prosecute this subject to a greater extent, may be referred to Long's Astronomy, 2 vols., 4to.—Robison's Mechanical Philosophy, vol. 1.—Dr. Pearson's Introduction to Practical Astronomy, comprising descriptions of Telescopes, Equatorials, Quadrants, and other astronomical instruments, 2 large vols., 4to., with numerous engravings of instruments.—Vince's complete System of Astronomy, 3 vols., 4to.—La Lande Astronomie, 3 vols., 4to—and Biot's Traitie Elémentaire d'Astronomie Physique. A comprehensive work on *Descriptive Astronomy*, detailing in a popular manner, all the facts which have been ascertained respecting the scenery of the heavens, accompanied with a variety of striking delineations, and interspersed with appropriate moral reflections, accommodated to the general reader, is a *desideratum* which we trust will be in some measure supplied by the two volumes we lately published, entitled "Celestial Scenery," and the "Sidereal Heavens," which have already passed through several editions, and have been republished in different parts of America.

SELECT BOOKS ON NATURAL PHILOSOPHY.

Hauy's Elementary Treatise on Natural Philosophy, translated by Dr. O. Gregory, 2 vols., 8vo. This translation contains a number of valuable notes by the translator.—Ferguson's Lectures on Select subjects in Mechanics, etc., by Sir D. Brewster, 2 vols., 8vo., with a vol. of plates. The Appendix to this work, by Sir D. Brewster, contains a mass of valuable information on Mechanics, Hydraulics, Dialing, and the construction of *Optical Instruments;* beside a variety of illustrative notes interspersed through the work, which comprises a detailed account of the recent discoveries in Experimental Philosophy.—Nicholson's Introduction to Natural Philosophy, 2 vols., 8vo.—Cavallo's Complete Treatise on Natural and Experimental Philosophy, 4 vols., 8vo.— Martin's Philosophia Britannica, 3 vols., 8vo.; his Gentleman and Lady's Philosophy; 3 vols., 8vo.; and his Philosophical Grammar, 1 vol., 8vo.—Herschel's Preliminary Discourses on the study of Natural Philosophy.—Lardner's Hydrostatics, Mechanics, and Pneumatics.—Professor Quetelet's Facts, Laws, and Phenomena of Natural Philosophy.—Partington's Manual of Natural and Experimental Philosophy, 2 vols., 8vo.—Sir D Brewster's Treatise on Optics.—Smith's Complete System of Optics, 2 vols., 4to., with 93 plates, containing 941 figures, 1738.—Arnot's Elements of Physics, 2 vols., 8vo.—Gregory's Economy of Nature, 3 vols, 8vo.; and his Lectures on Experimental Philosophy, Astronomy, and Chemistry, 2 vols., 12mo.—Joyce's Letters on Experimental Philosophy, 2 vols., 12mo.; and his Scientific Dialogues, 18mo.—Adams' Lectures on Natural and Experimental Philosophy, 4 vols., 8vo., with a vol. of plates.—Young's Lectures on Natural Philosophy, 2 vols., 8vo.—Walker's System of familiar Philosophy, 4to., in 12 lectures, with 47 4to. engravings.—Conversations on Natural Philosophy by the author of Conversations on Chemistry, one thick vol., 12mo., with 23 engravings.—Blair's Grammar of Natural Experimental Philosophy, especially the late editions, contains (at a small price), a comprehensive view of the principal departments of Philosophy, including Astronomy, Geology, Chemistry, Meteorology, etc.—Euler's Letters to a German Princess, 2 vols., 8vo., contains a popular view of the most interesting subjects connected with Natural and Experimental Philosophy, Logic, and Ethics. This work is distinguished by a vein of dignified and scriptural piety, which runs through every part of it. Euler was one of the most distinguished Philosophers and Mathematicians of his day. He died in 1783, at the age of 77. An edition of this work, containing *notes by Sir D. Brewster*, has been published. These notes are excellent, so far as they extend; but it is to be regretted that they are so sparingly distributed, and that the passages suppressed by M. Condorcet and De la Croix, which were restored by Dr. Hunter, who translated the work, and the notes of the French and English editors, are for the most part discarded. As a work of general information in relation to the physical sciences and other useful departments of knowledge, Chambers's *Information for the People* may be recommended to common readers, as a very useful and comprehensive compend of Science, History, Civil and Natural Geography, Vegetable and Animal Physiology, Chemistry, Electricity, Magnetism, etc. It is the cheapest book that has hitherto been published, when we consider the quantity of letter-press, and the vast mass of information it contains.

Notwithstanding the numerous excellent treatises which are to be found on this subject, a comprehensive work on experimental Philosophy, blended with sketches of those parts of natural history which are connected with it, and enlivened with appropriate reflections on the peculiar agencies of Deity, which appear in the various processes of nature—is still wanting to interest the general reader, and to attract his attention to this department of knowledge. Were philosophers, in their discussions of natural science, more frequently to advert to the agency of the Deity, and to point out the Religious and Philanthropic purposes to which modern discoveries might be applied, they might be the means of promoting, at the same time, the interests both of science and religion, by alluring general readers to direct their attention to such objects, and by removing those groundless prejudices which a great proportion of the Christian world still entertain against philosophical studies. About the period when Boyle, Ray, Derham, Nieuwentyt, Whiston, Addison, the Abbe Pluché, and other Christian philosophers flourished, more attention seems to have been paid to this subject than at present. Since the middle of the last century, the piety of philosophers appears to have been greatly on the decline. It is to be hoped that it is now beginning to experience a revival. But whatever may be the varying sentiments and feelings of mere philosophers, in reference to the agencies of the material system, "all the works of God *invariably* speak of their Author," to the humble and enlightened Christian; and if he be directed to contemplate the order of nature with an eye of intelligence, he will never be at a loss to trace the footsteps and the attributes of his Father and his God.

SELECT BOOKS ON CHEMISTRY

Davy's Elements of Chemical Philosophy, 8vo.—Ure's Dictionary of Chemistry, on the basis of Mr. Nicholson's, 1 large vol., 8vo.—Henry's Epitome of Chemistry, 2 vols., 8vo.—Accum's Chemistry, 2 vols., 8vo.—Thomson's System of Chemistry, 4 vols., 8vo.—Murray's System of Chemistry, 4 vols., 8vo., and Appendix.—Kerr's Translation of Lavoisier's Elements of Chemistry, 8vo.—Chaptal's Chemistry applied to the Arts, 4 vols., 8vo.—Fourcroy's Chemistry, 4 vols.—Accum's Chemical Amusements, and Griffin's Chemical Recreations, contain a description of a variety of interesting chemical facts, and amusing experiments.—Gurney's Lectures on the Elements of Chemical Science, 8vo.—Mackenzie's One Thousand Experiments in Chemistry, etc.—Mitchell's Dictionary of Chemistry.—Graham's Chemical Catechism.—Donovan's Treatise on Chemistry, in Lardner's Cyclopedia.—Turner's Chemistry.—Conversations on Chemistry, by a Lady, 2 vols., 12mo.—Joyce's Dialogues on Chemistry, 2 vols., 18mo.—Parke's Rudiments of Chemistry, 18mo, and his Chemical Catechism, 8vo. The four works last mentioned may be recommended as popular introductions to the study of this science.—Parke's Rudiments and Catechism are distinguished by their constant reference to the agency of the Deity, and by the anxiety which the author displays to fix the attention of his readers on the evidences of benevolent design which appear in the constitution of nature. The numerous notes appended to the Chemical Catechism embody a great variety of interesting facts in reference to the economy of nature, and the processes of the arts. To this amiable and intelligent writer I feel indebted for several of the chemical facts stated in this volume.

As the science of Chemistry is making rapid progress in its investigations and discoveries—the latest editions of the works referred to, and all others on the same subject, are generally to be preferred. The same remark is applicable to almost all the works connected with the physical sciences. But, with the exception of new discoveries, many of the works published twenty or thirty years ago, are worthy of being consulted, and are, in some respects, superior to more recent publications. There are some works, on different branches of natural science, published nearly a century ago, which give more full and clear descriptions of certain scientific facts than are to be found in many of our modern publications: and therefore such works ought not to be considered as altogether obsolete. It is of some importance to the student of science to be possessed of several treatises on the same subject; as certain principles or facts which may be vaguely stated, or imperfectly explained by one author, may be more fully and clearly elucidated by another

CELESTIAL SCENERY;

OR,

THE WONDERS

OF

THE PLANETARY SYSTEM DISPLAYED;

ILLUSTRATING

THE PERFECTIONS OF DEITY

AND A PLURALITY OF WORLDS.

PREFACE.

The following work is intended for the instruction of general readers, to direct their attention to the study of the heavens, and to present to their view sublime objects of contemplation. With this view the author has avoided entering on the more abstruse and recondite portions of astronomical science, and confined his attention chiefly to the exhibition of *facts*, the foundation on which they rest, and the reasonings by which they are supported. All the prominent facts and discoveries connected with descriptive astronomy, in so far as they relate to the planetary system, are here recorded, and many of them exhibited in a new point of view; and several new facts and observations are detailed which have hitherto been either unnoticed or unrecorded.

The results of hundreds of tedious calculations have been introduced respecting the solid and superficial contents of the different planets, their satellites, and the rings of Saturn; their comparative magnitudes and motions, the extent of their orbits, the apparent magnitudes of bodies in their respective firmaments, and many other particulars not contained in books of astronomy, in order to produce in the minds of common readers definite conceptions of the magnitude and grandeur of the solar system. The mode of determining the distances and magnitudes of the celestial bodies is explained, and rendered as perspicuous and popular as the nature of the subject will admit; and the prominent arguments which demonstrate a plurality of worlds are considered in all their bearings, and illustrated in detail.

One new department of astronomical science, which has hitherto been overlooked, has been introduced into this volume, namely, *the scenery of the heavens as exhibited from the surfaces of the different planets and their satellites*, which forms an interesting object of contemplation, and, at the same time, a presumptive argument in favor of the doctrine of a plurality of worlds.

The author, having for many years past been a pretty constant observer of celestial phenomena, was under no necessity of adhering implicitly to the descriptions given by preceding writers, having had an opportunity of observing, through some of the best reflecting and achromatic telescopes, the greater part of the phenomena of the solar system which are here described.

Throughout the volume he has endeavored to make the facts he describes bear upon the illustration of the Power, Wisdom, Benevolence, and the Moral Government of the Almighty, and to elevate the views of the reader to the contemplation of HIM who sits on the throne of the universe, "by whom the worlds were framed," and who is the Source and Center of all felicity.

In prosecuting the subject of Celestial Scenery, the author intends, in another volume, to carry forward his survey to the STARRY HEAVENS and other objects connected with astronomy. That volume will embrace discussions relative to the number, distance, and arrangement of the stars; periodical and variable stars; new and temporary stars; double and triple stars; binary systems; stellar and planetary nebulæ; the comets, and other particulars; accompanied with such reflections, as the contemplation of such august objects may suggest. The subject of a plurality of worlds will likewise be prosecuted, and additional arguments, derived both from reason and Revelation, will be adduced in support of this position. The practical utility of astronomical studies, their connection with religion, and the views they unfold of the perfections and the empire of the Creator, will also be the subject of consideration. And should the limits of a single volume permit, some hints may be given in relation to the *desiderata* in astronomy, and the means by which the progress of the science may be promoted, together with descriptions of the telescope, the equatorial, and other instruments, and the manner of using them for celestial investigation.

BROUGHTY FERRY, NEAR DUNDEE.

CONTENTS.

INTRODUCTION.

Page

Objects and sublimity of the science of astronomy. Ignorance of former ages on this subject. Modern Discoveries—object of this work 9

CHAPTER I.

ON THE GENERAL APPEARANCE AND APPARENT MOTIONS OF THE STARRY HEAVENS.

Ignorance of the bulk of mankind in regard to the apparent motions of the heavens. Deficiencies in our modes of education. Innate curiosity of the young. Apparent motions and phenomena of the nocturnal heavens. How to find the pole-star. Description of *Ursa Major* and *Minor*. Situations of some of the principal stars. Appearance of the firmament in southern latitudes. Magnificence of the starry heavens. Proofs of the earth's rotation. Utility of the stars. Measures of the celestial sphere.................................. 11

CHAPTER II.

ON THE GENERAL ARRANGEMENT OF THE PLANETARY SYSTEM.

Ptolemaic system—its complexity and futility. Copernicus. System of Copernicus—its important bearings. Arguments to prove the truth of this system, and of the earth's annual motion, *illustrated at large*. Motion of the earth a sublime object of contemplation......... 19

CHAPTER III.

ON THE MAGNITUDES, MOTIONS, AND OTHER PHENOMENA OF THE BODIES CONNECTED WITH THE SOLAR SYSTEM.

1. *The Planet Mercury.*

Its period—elongation—transits—mountains—*intensity of light*—*temperature*—magnitude and population—rate of motion—mass and density—eccentricity of orbit, &c................ 27

2. *The Planet Venus.*

Form of the Planetary orbits. Explanation of astronomical terms. General appearance, phases, and apparent motions of Venus. May be seen at its *superior* conjunction. Observations on in the day-time. Discoveries on by the telescope. Views of by Cassini, Bianchini, Maraldi, Schroeter, and others. Its mountains and atmosphere. Its supposed satellite—its transits—extent of surface—quantity of light—temperature—distance—rate of motion, density, &c.. 29

3. *The Earth considered as a Planet.*

Its spheroidal figure, and how ascertained—general aspect of its surface—appearance if viewed from the moon—its *internal structure* and *density*—its variety of *seasons*—general reflections on—its tropical and sidereal year, and various other particulars.......................... 39

4. *The Planet Mars.*

Peculiar phenomena of the *superior* planets. Conjunctions, oppositions, and phases of Mars—distance, motion, apparent diameter, and extent of its orbit—telescopic views of its surface—

its atmosphere—conclusions respecting its physical constitution—its superficial contents—proportion of light—whether it have a secondary attendant, &c. 45

5. *The Planets Vesta, Juno, Ceres, and Pallas.*

History of their discovery. Notice of Dr. Olbers. Magnitude, distances, periods, and other phenomena of these planets—their *peculiarities*—inclination and eccentricity of orbits, &c., &c. *Conclusions respecting the nature of these planets.* Remarks in reference to the Divine government. Summary—concluding reflections.. 137

APPENDIX.

Descriptions of Celestial phenomena, and of the positions and aspects of all the planets during the years 1838 and 1839 137

CELESTIAL SCENERY.

INTRODUCTION.

Astronomy is that department of knowledge which has for its object to investigate the motions, the magnitudes, and distances of the heavenly bodies; the laws by which their movements are directed, and the ends they are intended to subserve in the fabric of the universe. This is a science which has in all ages engaged the attention of the poet, the philosopher, and the divine, and been the subject of their study and admiration. Kings have descended from their thrones to render it homage, and have sometimes enriched it with their labors; and humble shepherds, while watching their flocks by night, have beheld with rapture the blue vault of heaven, with its thousand shining orbs, moving in silent grandeur, until the morning star announced the approach of day. The study of this science must have been coeval with the existence of man; for there is no rational being who has for the first time lifted his eyes to the nocturnal sky, and beheld the moon walking in brightness amidst the planetary orbs and the host of stars, but must have been struck with admiration and wonder at the splendid scene, and excited to inquiries into the nature and destination of those far-distant orbs. Compared with the splendor, the amplitude, the august motions, and the ideas of infinity which the celestial vault presents, the most resplendent terrestrial scenes sink into inanity, and appear unworthy of being set in competition with the glories of the sky.

When, on a clear autumnal evening, after sunset, we take a serious and attentive view of the celestial canopy; when we behold the moon displaying her brilliant crescent in the western sky; the evening star gilding the shades of night; the planets moving in their several orbs; the stars, one after another, emerging from the blue ethereal, and gradually lighting up the firmament until it appear all over spangled with a brilliant assemblage of shining orbs; and particularly when we behold one cluster of stars gradually descending below the *western* horizon, and other clusters emerging from the *east*, and ascending, in unison, the canopy of heaven; when we contemplate the whole celestial vault, with all the shining orbs it contains, moving in silent grandeur, like one vast concave sphere, around this lower world and the place on which we stand—such a scene naturally leads a reflecting mind to such inquiries as these: Whence come those stars which are ascending from the east? Whither have those gone which have disappeared in the west? What becomes of the stars during the day which are seen in the night? Is the motion which appears in the celestial vault *real*, or does a motion in the earth itself cause this appearance? What are those immense numbers of shining orbs which appear in every part of the sky? Are they mere studs or tapers fixed in the arch of heaven, or are they bodies of immense size and splendor? Do they shine with borrowed light, or with their own native luster? Are they placed only a few miles above the region of the clouds, or at immense distances beyond the range of human comprehension? Can their distance be ascertained? Can their bulk be computed? By what laws are their motions regulated? and what purposes are they destined to subserve in the great plan of the universe? These, and similar questions, it is the great object of astronomy to resolve, in so far as the human mind has been enabled to prosecute the path of discovery.

For a long period, during the infancy of science, comparatively little was known of the heavenly bodies excepting their apparent motions and aspects. Instead of investigating with care their true motions, and relative distances and magnitudes, many of our ancestors looked up to the sky either with a brute unconscious gaze, or viewed the heavens as the book of fate, in which they might read their future fortunes, and learn, from the signs of the zodiac, and the conjunctions and other aspects of the planets, the temperaments and destinies of men and the fate of empires. And even to this day, in many countries, the fallacious art of prognosticating fortunes by the stars is one of the chief uses to which the science of the heavens is applied. In the ages to which I allude, the world in which we dwell was considered as the largest body in the universe. It was supposed to be an immense plane, diversified with a few inequalities, and stretching in every direction to an indefinite extent. How the sun penetrated or surmounted this immense mass of matter every morning, and what became of him in the evening—whether, as the poets assert, he extinguished himself in the western ocean, and was again lighted up in the eastern sky in the morning—many of them could not determine.—*Below* this mass of matter we call the earth, it was conceived that nothing but darkness and empty space, or the regions of Tartarus, could exist. The stars which gild the concave of the firmament *above* were considered only as so many bright studs fixed in a crystalline sphere, which carried them round every day to emit a few glimmering rays, and to adorn the ceiling of our terrestrial habitation. Above the visible firmament of heaven, and far beyond the ken of mortal eye, the Deity was supposed to have fixed his special residence, among myriads of superior intelligences. The happiness, the preservation, and the moral government of the human race were supposed to be the chief business and object of the Deity, to which all his decrees in eternity past, and all his arrangements in relation to eternity to come, had a special and almost exclusive reference. Such ideas are still to be found, even in the writings of Christian divines, at a period no further back than the sixteenth century.

To hazard the opinion that the plans of the Almighty embraced a much more extensive range—

that other beings, analogous to men, inhabited the planetary or the starry orbs, and that such beings form by far the greater part of the population of the universe—would have been considered as a heresy in religion, and would probably have subjected some of those who embraced it to the anathemas of the church, as happened to Spigelius, bishop of Upsal, for defending the doctrine of the antipodes, and to Galileo, the philosopher of Tuscany, for asserting the motion of the earth. The ignorance, the intolerance, and the contracted views to which I allude, are, however, now, in a great measure, dissipated. The light of science has arisen, and shed its benign influence on the world. It has dispelled the darkness of former ages, extended our prospects of the grandeur and magnificence of the scene of creation, and, in conjunction with the discoveries of revelation, has opened new views of the perfections and moral government of the Almighty. In the progress of astronomical science, the distances and magnitudes of many of the celestial bodies began to be pretty nearly ascertained; and the invention of the *telescope* enabled the astronomer to extend his views into regions far beyond the limits of the unassisted eye, and to discover myriads of magnificent globes formerly hid in the unexplored regions of immensity. The planetary orbs were found to bear a certain resemblance to the earth, having spots and dark streaks of different shades upon their surfaces; and it was not long in being discovered that, notwithstanding their apparent brilliancy, they are, in reality, opaque globes, which derive all their light and luster from the sun. The planet Venus, in different parts of its orbit, was observed to exhibit a gibbous phase, and the form of a crescent similar to the moon, plainly indicating that it is a dark globe, enlightened only on one side by the rays of the sun.—The moon was perceived to be diversified with hills and valleys, caverns, rocks, and plains, and ranges of mountains of every shape, but arranged in a manner altogether different from what takes place in our sublunary sphere. The sun, which was generally supposed to be a ball of liquid fire, was found to be sometimes covered with large dark spots, some of them exceeding in size the whole surface of the terraqueous globe, and giving indications, by their frequent changes and disappearance, of vast operations being carried on upon the surface and in the interior of that magnificent luminary. Hundreds of stars were descried where scarcely one could be perceived by a common observer; and as the powers of the telescope were increased, thousands more were brought to view, extending in every direction, from the limits of unassisted vision throughout the boundless extent of space.

It is natural for an intelligent observer of the universe to inquire into the final causes of the various objects which exist around him. When he beholds the celestial regions filled with bodies of an immense size, arranged in beautiful and harmonious order, and performing their various revolutions with regularity and precision, the natural inquiry is, For what end has the Deity thus exerted his wisdom and omnipotence? What is the ultimate destination of those huge globes which appear in the spaces of the firmament? Are these vast masses of matter suspended in the vault of heaven merely to diversify the voids of infinite space, or to gratify a few hundreds of terrestrial astronomers in peeping at them through their glasses? Is the Almighty to be considered as taking pleasure in beholding a number of splendid lamps, hung up throughout the wilds of immensity, which have no relation to the accommodation and happiness of intelligent minds? Has he no end in view corresponding to the magnificence and grandeur of the means he has employed! Or, are we to conclude that his wisdom and goodness are no less conspicuously displayed than his omnipotence in peopling those vast bodies with myriads of intelligent existences of various orders, to share in his beneficence and to adore his perfections? This last deduction is the only one which appears compatible with any rational ideas we can entertain of the wisdom and intelligence of the Eternal Mind, and the principles of the Divine government.

This opinion is now very generally entertained by those who have turned their attention to the subject. But it is frequently admitted on grounds that are too general and vague; on the authority of men of science, or on the mere ground that the planets and stars are bodies of immense size; and hence it is only considered as a *probable* opinion, and *a thorough conviction* of its truth is seldom produced in the mind.

In the following work it shall be our endeavor to show that the arguments which may be brought forward to establish the doctrine of a plurality of worlds have all the force of a *moral demonstration;* that they throw a luster on the perfections of the Divinity; and that the opposite opinion is utterly inconsistent with the every idea we ought to entertain of an All-wise and Omnipotent Intelligence.

In order to the full illustration of this subject, it will be necessary to take a pretty minute and comprehensive view of all the known facts in relation to the heavenly bodies; and while these facts will be made to bear upon the object now proposed, they will likewise tend to exhibit the scenery of the heavens, and to elucidate many of the prominent truths and principles connected with descriptive astronomy. In the progress of our discussions, we shall descend into many minute particulars which are generally overlooked by writers on the subject of astronomy, and shall introduce several original observations and views on this subject which have not hitherto been particularly detailed.

CHAPTER I.

ON THE GENERAL APPEARANCE AND APPARENT MOTIONS OF THE STARRY HEAVENS.

Before proceeding to a particular description of the real magnitudes, motions, and phenomena of the heavenly bodies, it may not be improper to take a brief survey of the general appearance and apparent motions of the celestial vault, as they present themselves to the eye of a common observer.

It is of importance to every one who wishes to acquire a clear idea of the principles of astronomy and the phenomena of the heavens, that he contemplate with his own eyes the *apparent* aspects and revolutions of the celestial bodies before he proceeds to an investigation of the *real* motions, phenomena, and arrangements which the discoveries of science have led us to deduce. From want of attention to this circumstance, there are thousands of smatterers in the science of astronomy who never acquire any clear or comprehensive ideas on this subject; and who, instead of clearly perceiving the relations of the heavenly orbs from their own observation, rely chiefly on the assertions of their instructors, or the vague descriptions to be found in elementary books. It is amazing how many intelligent men there are among us who would not wish to be considered altogether ignorant of modern astronomy, have never looked up to the celestial vault with fixed attention; have never made repeated observations to discover its phenomena; and cannot tell, from their own survey, what are the various motions it exhibits. There are thousands and ten thousands who have gazed on a clear evening sky, at certain intervals, during a period of many years, yet can tell no more about the glorious scene around them than that they behold a number of shining points twinkling in every direction in the canopy above. Whether these bodies shift their positions with regard to each other, or remain at the same relative distances; whether any of them appear in motion, while others appear at rest; whether the whole celestial canopy appears to stand still, or is carried round with some general motion; whether all the stars which are seen at six o'clock in the evening are also visible at twelve at midnight; whether the stars rise and set, as the sun and moon appear to do; whether they rise in the east, or north-east, or in any other quarter; whether some rise and set regularly, while others never descend below the horizon; whether any particular stars are occasionally moving backward or forward, and in what parts of the heavens they appear; whether there are stars in our sky in the daytime as well as during night; whether the same clusters of stars are to be seen in summer as in winter? To these and similar questions there are multitudes who have received a regular education, and who are members of a Christian church, who could give no satisfactory answers. And yet almost every one of these inquiries could be satisfactorily answered, in the course of a few evenings, by any man of common understanding who directed his attention for a few hours to the subject, and that, too, without the knowledge of a single scientific principle. He has only to open his eyes, and to make a proper use of them; to fix his attention on the objects before him; to make one observation after another; and to compare them together; and to consider that "the works of the Lord are *great*," and that they ought "to be sought out [or seriously investigated] by all those who have pleasure therein."

If this representation be admitted as just, what a striking idea does it present of the *apathy* and indifference of the greater part of mankind in regard to the most astonishing and magnificent display which the Creator has given of himself in his works! Had we an adequate conception of all the scenes of grandeur, and the displays of intelligence and omnipotent power, which a serious contemplation of a starry sky is calculated to convey, all the kingdoms of this world would sink into comparative insignificance, and all their pomp and splendor appear as empty as the bubbles of the deep. It is amazing that *Christians*, in particular, should, in so many instances, be found overlooking such striking displays of Divine perfection as the firmament opens to our view, as if the most august works of the Creator, and the most striking demonstration of his "eternal power and godhead," were unworthy of their regard; while we are commanded, in Scripture, to "lift up our eyes on high, and consider Him who hath created these orbs, who bringeth forth their hosts by number," and who guides them in all their motions "by the greatness of his strength." "The heavens," says the Psalmist, "declare the glory of the Lord, and the firmament showeth his handiwork." Though these luminaries "have no speech nor language," though "their voice is not heard" in articulate sounds, yet, as they move along in *silent* grandeur, they declare to every reflecting beholder that "the hand that made them is Divine."

One great cause of this indifference and inattention is to be found in the want of those habits of observation and reflection which ought to be formed in early life by the instructions imparted in the family circle and at public seminaries. Children, at a very early age, are endowed with the principle of curiosity, and manifest an eager desire to become acquainted with the properties and movements of the various objects which surround them; but their curiosity is, in most instances, improperly directed; they are seldom taught to make a right use of their senses; and when they make inquiries in reference to the appearances of nature, their curiosity is too frequently repressed, until, at length, habits of inattention and indifference take possession of their minds. A celebrated author represents his pupil as expressing himself in the following manner:—"I shall freely tell you the things which frequently occur to my mind, and often perplex my thoughts. I see the heavens over my head, and tread on the earth with my feet; but I am at a loss what to think of that *mighty concave* above me, or even of this very earth I walk upon. I often think whether the earth may not stretch out in breadth to immensity, so as, if one was to travel it over, one should never be able to get to the *end* of the earth, but always find room to continue the journey; nor can I satisfy myself as to the depth of the earth, whether it has any bottom; and, if so, what it can be that is below the earth. As to the heaven, I need say nothing: every change that happens, and every object seen there, perplex me with doubts and fruitless guesses. I often wonder how the sun moves over so large a space every day, and yet seems not to stir out of his place. I would know where he goes beyond the mountains in the evening; what becomes of him in the night-time; whether he makes his way through the thickness of the earth, or the depth of the sea, and so always shows himself again from the east next morning. It seems strange that, being so small a body as he is, he should still be seen everywhere, and still of the same bigness. The various nature of the *moon* seems yet more perplexing; to-night, perhaps, you can scarce discern her; but, in a few days, she becomes larger than the body of the sun itself. In a little time after, she decays, and, at last, wears quite away; yet she recovers again. In a word, she is never the same, and yet still becoming what she was before. What means that multitude of stars scattered over the face of the whole sky, whose number is so great that it is become proverbial? There are other things I want to be informed of, but these are the main difficulties which exercise my thoughts, and perplex my mind with endless doubting."

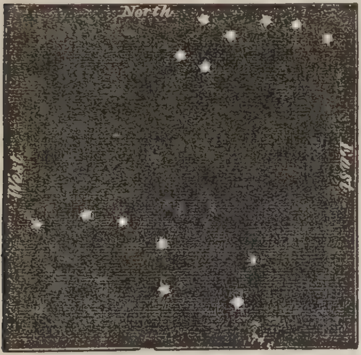
Were the young, or any other class of persons, led to such reflections as these, and were their doubts and inquiries resolved, so far as our knowledge extends, we should have a hundred intelligent observers of the phenomena of the universe for one that is found in the present state of society. But, instead of answering their inquiries and gratifying their natural curiosity, we not unfrequently tell them that they are troublesome with their idle questions; that they ought to mind their grammar and parts of speech, and not meddle with philosophical matters until they be many years older; that such subjects cannot be understood until they become men; and that they must be content to remain in ignorance for ten or twelve years to come. Thus we frequently display our own ignorance and inattention, and thus we repress the natural desire for knowledge in the young, until they become habituated to ignorance, and until the uneasy sense arising from curiosity and unsatisfied desire has lost its edge, and a desire for sensual or vicious pleasure usurps its place. I recollect, when a boy of about seven or eight years of age, frequently musing on such subjects as those to which we have now alluded. I sometimes looked out from a window, in the daytime, with fixed attention, on a pure azure sky, and sometimes stretched myself on my back on a meadow, or in a garden, and looked up to the zenith to contemplate the blue ethereal. On such occasions a variety of strange ideas sometimes passed through my mind. I wondered how far the blue vault of heaven might extend; whether it was a solid transparent arch, or empty space; what would be seen could I transport myself to the highest point I perceived; and what display the Almighty made of himself in those regions so far removed from mortal view. I asked myself whether the heavens might be bounded on all sides by a solid wall; how far this wall might extend in thickness; or whether there was nothing but empty space, suppose we could fly forever in any direction. I then entered into a train of inquiries as to what would have been the consequences had neither heaven nor earth been made, and had God alone existed in the boundless void. Why was the world created? What necessity was there why God himself should exist? And why was not all one vast blank, devoid of matter and intelligence? My thoughts ran into wild confusion; they were overwhelming, and they became even oppressive and painful, so as to induce me to put a check to them, and to hasten to my playful associates and amusements. But although my relatives were more intelligent than many of their neighbors, I never thought of broaching such ideas, or of making any inquiries of them respecting the objects which had perplexed my thoughts; and, even if I had, it is not likely I should have received much satisfaction. Such views and reflections are, perhaps, not uncommon in the case of thousands of young people. I mention these things to show that the youthful mind, in consequence of the innate desire of knowledge with which it is endowed, is often in a state peculiarly adapted for receiving instruction on many important subjects, and for becoming an intelligent observer of the economy of nature, were it not that our methods of instruction hitherto, both in public and in private, instead of gratifying juvenile curiosity, have frequently tended to counteract the natural aspirations of the opening mind.

But, leaving such reflections and digressions, let us now take a general view of the motions of and phenomena of the nocturnal heavens.

Let us suppose ourselves under the open canopy of heaven in a clear night, at six o'clock in the evening, about the first of November. I fix upon this period, because the *Pleiades*, or seven stars, which are known to every one, are then visible during the whole night, and because, at this season of the year, the most brilliant fixed stars, and the more remarkable constellations, are above the horizon in the evening. Turning our eyes, in the first place, toward the *eastern* quarter of the heavens, we shall see the seven stars just risen above the horizon, in a direction about half way between the east and the north-east points, or east-north-east. North-west from the seven stars, at the distance of thirty degrees, a very bright star, named *Capella*, may be perceived at an elevation of about eighteen degrees above the horizon. Directing our view toward the south, we shall perceive a pretty bright star, with a small star on the north and another on the south of it, which has just passed the meridian. This star is called *Altair*, and belongs to the constellation *Aquila.*—It is nearly south, at an elevation of forty-six degrees, or about half-way between the horizon and the zenith. About thirty-three degrees north from Altair, and a little farther to the west, is the brilliant star *Lyra*, belonging to the *Harp*. Looking to the west, a bright star, named *Arcturus*, will be seen about fifteen degrees above the horizon, a very little to the north of the western point. Turning our eyes in a northerly direction, the constellation *Ursa Major*, or the Great Bear, presents itself to view. This cluster of stars is sometimes distinguished by the name of the *Plow*, or *Charles's Wain*, and is known to almost every observer. The relative positions of the prominent stars it contains are represented in the following figure. At the time of the evening now supposed, it appears a little to the westward of the northern point of the heavens, the two eastern stars of the square being about eighteen degrees west from that point. These two stars, the uppermost of which is named *Dubhe*, and the lower one *Merak*, are generally distinguished by the name of the *Pointers*, because they *point*, or direct our eye toward the pole-star.

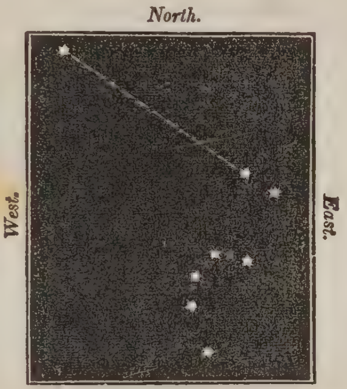
The seven stars in the lower part of the figure are the prominent stars which constitute the tail and the body of the Great Bear. The first of these, reckoning from the left, is termed *Benetnasch*, the second *Mizar*, the third *Alioth*, the fourth *Megrez*, immediately below which is *Phad.* The other two stars to the right are the *Pointers*, alluded to above. If a line connecting these two stars be considered as prolonged upward to a considerable distance until it meet the first bright star, it directs us to the *pole-star*, which is the one nearest to the pole, and which, to a common observer, never seems to shift its position. The uppermost star in the figure toward the right hand represents the pole-star in its relative distance and position to the Great Bear. The distance between the two pointers, Dubhe and Merak, is about five degrees; and the distance between Dubhe, the uppermost of the pointers, and the pole-star, is about twenty-nine degrees; so that the space between Dubhe and the pole-star is nearly six times the distance between the two pointers. By attending to these circumstances, the distance between any two stars, when expressed in degrees, may be nearly ascertained by the eye. The six small stars in the upper part of the figure represent the constellation *Ursa Minor*, or the Lesser Bear, of which the pole-star forms the tip of the tail.—They resemble the configuration of the stars in the Great Bear, only they are on a smaller scale, and in a reversed position.*

Fig. 1.



Having now fixed on certain stars or points in the heavens as they appear about six in the evening, and marked their relative positions, let us take another view of the celestial vault as it appears about ten o'clock the same evening, or the first clear evening afterward. We shall then find that the seven stars have risen to a considerable elevation, and are nearly half way between the eastern horizon and the south; that the *Bull's-eye*, a bright ruddy star, which was before invisible, is now seen a little to the eastward of the Pleiades; and that bright constellation *Orion*, which in the former observation was below the horizon, is now distinctly visible in the east and south-east; and the star *Capella* midway between the horizon and the zenith. The stars *Altair* and *Lyra*, which were before nearly south, have descended more than half-way toward the western horizon.—The star Arcturus is no longer visible, having sunk beneath the horizon; and many stars in the eastern quarter of the heavens, which were formerly unseen, now make their appearance at different elevations. The stars of the Great Bear, particularly the two pointers, which were formerly to the west of the north point, have now passed to the east of it. At twelve o'clock, midnight, their position may be thus represented.

Fig. 2.



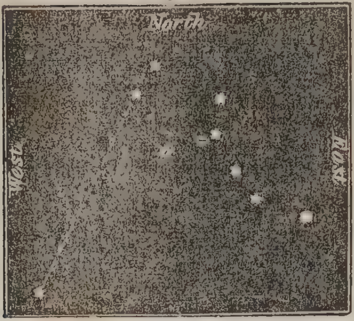
The pointers now appear considerably to the eastward of the north point, and considerably more elevated than before, while the stars in the tail appear much lower. About three o'clock next morning the pointers will appear nearly due east from the pole-star, and at the same elevation above the horizon; and the other stars in that constellation will be seen hanging, as it were, nearly perpendicularly below them. At this hour the Pleiades, or seven stars, will appear to have moved twenty-five degrees past the meridian to the west, and the brilliant constellation Orion will be seen nearly due south. The bright star Capella now appears nearly in the zenith, or point directly over our heads; Lyra is in the horizon, nearly due north, and Altair has descended below the western horizon. At six in the morning, the seven stars will be seen in the west, only a short distance above the horizon; and all the other stars to the eastward of them will be found to have made a considerable progress toward the west.—At this hour the stars of the Great Bear will appear near the upper part of the heavens, and the pointers not far from the zenith. Their position at this time is shown in the following figure.

Here the pointers appear elevated a great way *above* the pole-star, whereas, in the observation at six in the evening, the whole constellation appeared far *below* it. At eight in the morning, the whole of the constellation would be seen nearly overhead, were the stars then visible; at twelve, noon, it would appear toward the west, at a considerable elevation; and at six in the evening, it would again return to its former position, as noted

---

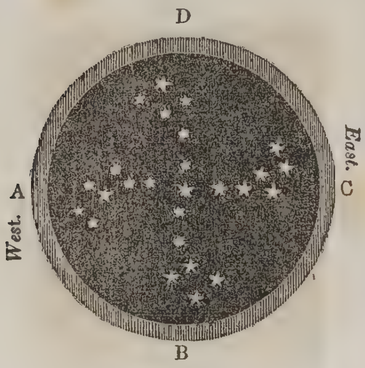
*In these observations, the observer is supposed to be placed nearly in 52° north latitude, which is nearly the latitude of London. Those who reside in latitudes between 40° and 45°, as the inhabitants of Philadelphia, New York, Hartford, Boston, Montreal, Madrid, Rome, etc., would require to postpone their observations until a little after half-past six in the evening, and to make a small allowance for the elevations, above stated, of certain stars above the horizon. In most other respects, the appearance of the heavens, to the inhabitants of such places, will be the same as here described.

Fig. 3.



in our first observation. The following figure represents the position of *Ursa Minor*, or the Lesser Bear, at four different periods during twenty-four hours.

Fig. 4.



At six in the evening, about the beginning of November, *Ursa Minor* will be nearly in the position represented on the left at *A*, nearly straight west from the pole-star, which appears in the center. Six hours afterward, or at twelve, midnight, it will appear below the pole, in the position marked *B;* at six next morning, it will appear opposite to its first position, as represented on the right at *C;* at twelve, noon, it will appear above the pole, as represented at *D;* but in this position it cannot be seen in November, or during the winter months, as the stars at that time of the day are eclipsed by the light of the sun. At six in the evening it again returns to its former position. Such are the general appearance and apparent motions of all the stars in the northern hemisphere, within fifty-two degrees of the pole, to a spectator situated in 52° of north latitude. They all appear to perform a circuit, in the course of twenty-four hours, around a point which is the center of their motion, near to which is the pole-star. All the stars within this range never set, but appear to describe complete circles, of different dimensions, around the pole and above the horizon. When they are in the lower part of their course, or beneath the pole, they appear to move from west to east; but when in the higher part of their course, their apparent motion is from east to west; and all their circuits are completed in exactly the same period of time, namely, twenty-three hours, fifty-six minutes, and four seconds.

Let us now consider the appearances which present themselves in the other quarters of the heavens. If we turn our eyes a little to the left of the south, near to that point of the compass called south-south-east, and observe a star near the horizon, such as the star *Fomalhaut*, in the Southern Fish, it will appear to rise to a very small altitude when it comes to the meridian, only about six degrees, and in about five hours it will set near the point south-south-west, having described a very small arc of a circle above the horizon. If we direct our attention to the south-east, and observe any bright star, such as Sirius, or the Dog-star, in the horizon, it will make a larger circuit over the southern sky, and will remain about nine hours above the horizon before it sets in the south-west. If we look due east, and see a star, such as Procyon in the constellation of the Lesser Dog, rising, it will remain about twelve hours above the horizon, and will set in the west. If we look to the north-east, and perceive any stars, such as *Castor* and *Pollux*, beginning to appear, they will make a large circuit round the heavens, such as the sun describes in the month of June, and, after the period of about eighteen hours, will set in the north-west.

Such are the general appearances and the apparent motions of the heavens which present themselves when viewed from our northern latitude. Were we to take our station near the Gulf of Guinea, in the island of Sumatra, or Borneo, in the Gallipago Isles, in the city of Quito, in South America, or on any other point of the globe near the equator, the motions of the stars would appear somewhat different. The pole-star, instead of being at a high elevation, as in our latitude, would be in the horizon. All the stars would appear to rise and set, and the time of their continuance above the horizon would be precisely the same. The stars which rise in the east would ascend to the zenith, and pass directly overhead, in the course of six hours; and in another six hours they would descend to the horizon, and set in the western point. The stars near the northern and southern points would appear to describe small semicircles above the horizon during the same time, and their motion would appear much slower. The Great Bear, which never sets in our latitude, would be above the horizon only during the one-half of its circuit. Many stars and constellations would appear in the southern quarter of the sky which we never see in our latitude. Every star would be found to remain exactly twelve hours above and twelve hours below the horizon, and all the visible stars in the firmament might, from such a position be perceived in the course of a year. Were we to take our station in the southern hemisphere, in Valdivia, Botany Bay, or Van Dieman's Land, the heavens would present a different aspect from any of those we have yet contemplated. The north pole-star, the Great Bear, and other neighboring constellations, would never appear above the horizon. Many of the stars which we now see in the south would appear in the north. The south pole would appear elevated about forty degrees above the horizon, and various clusters of stars would be seen revolving round it, as the Great Bear and other constellations do around the north pole. In fine, could we take our station at ninety degrees of north latitude, or, in other words, at the north pole of the world, we should just see one-half of the stars of heaven, and no portion of the other half would ever be visible. These stars would appear neither to rise nor set, nor yet to stand still. They would appear to move round the whole heavens, in circles parallel to the horizon, every twenty-four hours; and on every clear evening, all the stars that are ever visible in that hemisphere may be seen. The stars, however, that appear in a certain direction at any particular hour, will appear at the same elevation in the opposite direction, twelve hours afterward; and during nearly six months no stars will be seen in the sky.

The apparent motion of the heavens may at any time be perceived by fixing on any star that appears nearly in a line with a tree, a spire, or any other fixed object, and in the course of a few minutes its motion will be perceptible; or, fix a common telescope upon a pedestal, and direct it to any star, and in three or four minutes it will be seen to have passed out of the field of view. In the description now given, I have spoken of the *pole-star* as if it were actually the pole, or the most northerly point of the heavens. But it may be proper to state, that though it is the nearest large star to that point, it is not actually in the pole; it is somewhat more than a degree and a half from the polar point, and revolves around that point, in a small circle, every twenty-four hours. This motion may be perceived by directing a telescope of a moderate magnifying power to this star, and fixing it in that position, when, in the course of an hour or two, it will be found to have moved beyond the field of view.

All the observations above stated (excepting those supposed to have been made at the equator, and in southern latitudes) may be accomplished in the course of two or three evenings, without incurring the loss of a couple of hours; for each observation may be made in the space of five or ten minutes. Every inhabitant of the globe has an opportunity, if he choose, of observing the aspect of the heavens in the manner now described, excepting, perhaps, those who live in dark and narrow lanes, in large cities, where the sky is scarcely visible; the most unnatural situations in which human beings can be placed, and which ought no longer to remain as the abodes of men. And the man who will not give himself the trouble of making such observations on the starry heavens, deserves to remain in ignorance of the most sublime operations of the Creator.

Let us now consider what is the conclusion we ought to deduce from our observations respecting the apparent motions of the heavens. All the phenomena which we have described, when duly considered and compared together, conspire to show that *the whole celestial vault performs an apparent revolution round the earth*, carrying, as it were, all the stars along with it, in the space of twenty-four hours. This may be plainly demonstrated by means of a celestial globe, on which all the visible stars are depicted. When the north pole is elevated fifty-two degrees above the northern horizon, and the globe turned round on its axis, all the variety of phenomena formerly described may be clearly perceived.

Here, then, we have presented to view a scene the most magnificent and sublime. All the bright luminaries of the firmament revolving in silent grandeur around our world; not only the stars visible to the unassisted eye, but all the ten thousands and millions of stars which the telescope has enabled us to descry in every region of the heavens, for they all seem to partake of the same general motion. If we could suppose this motion to be *real*, it would convey to the mind the most magnificent and impressive idea which could possibly be formed of the incomprehensible energies of Omnipotence. For here we have presented to view, not only ten thousand times ten thousands of immense globes, far superior to the whole earth in magnitude, but the greater part of them carried round in their revolutions with a velocity that baffles the power of the most capacious mind to conceive. In this case, there would be millions of those vast luminaries, which behooved to move at the rate of several thousands of millions of miles *in the space of a second of time*. For in proportion to the distances of any of these bodies would be the rapidity of their motions. The nearest star would move more than fourteen hundred millions of miles during the time in which the pendulum of a clock moves from one side to another; but there are thousands of stars visible through our telescopes at least a hundred times more distant, and whose distance cannot be less than 2,000,000,000,000,000, or two thousand billions of miles. This forms the radius, or half diameter of a circle, whose circumference is about 12,500,000,000,000,000, or twelve thousand five hundred billions of miles. Around this circumference, therefore, the star behooved to move every day. In a sidereal day of twenty-three hours, fifty-six minutes, and four seconds, there are 86,164 seconds. Divide the number of miles in the circumference by the number of seconds in a day, and the quotient will be somewhat more than 145,000,000,000, or one hundred and forty-five thousand millions, which is the number of miles that such a star would move in the space of a second, or during the pulsation of an artery, were the celestial vault to be considered as really in motion; a rate of motion more than a hundred thousand millions of times greater than that of a cannon ball, and seven hundred thousand times more rapid than the motion of light itself, which is considered the swiftest motion in nature.

The idea of such astonishing velocities completely overpowers the human imagination, and is absolutely inconceivable. We perceive no objects or motions connected with our globe that can assist our imagination in forming any definite conceptions on this subject. The swiftest impulse that was ever given to a cannon ball, or any other projectile, sinks into nothing in the comparison. Were we transported to the planet Saturn, and placed on its equatorial regions, we should behold a stupendous arch, thirty thousand miles in breadth, and more than six hundred thousand miles in circumference, revolving around us every ten hours, at the rate of a thousand miles in a minute, and sixty thousand miles every hour.—But even this astonishingly rapid motion would afford us little assistance in forming our conceptions, as it bears no comparison with the motions to which we have now adverted. It becomes those persons, therefore, who refuse to admit the motion of the earth, to consider, and to ponder with attention, the only other alternative which *must be* admitted, namely, that all the bodies of the firmament move round the earth every day with such amazing velocities as have now been stated. If it appear wonderful that this globe of the land and water, with all its mighty cities and vast population, moves round its axis every day at the rate of a thousand miles an hour, how much more wonderful, and passing all comprehension, that myriads of huge globes should move round the earth in the same time with such inconceivable rapidity. If we reject the motion of the earth because it is incomprehensible and contrary to all our preconceived notions, we must, on the same ground, likewise reject the motion of the heavens, which is far more difficult to be conceived, and consequently fall into downright skepticism, and reject even the evidences of our senses as to what appears in the economy of nature. Such views and considerations, however, teach us that, in whatever point of view we contemplate the works of the Almighty, particularly the scenery of the heavens, the mind is irresistibly inspired with sentiments of admiration and wonder. To the vulgar eye as well as to the philosophic, "the heavens declare the glory of God." Their harmony and order evince his wisdom and intelligence; and the numerous bodies they contain, and the astonishing motions they exhibit, on whatever hypothesis they are contemplated, demonstrate both to the savage and the sage the existence of a power which no created being can control.

> "View the amazing canopy!
> The wide, the wonderful expanse!
> Let each bold infidel agree
> That God is there, unknown to chance."

We cannot, however, admit, in consistency with the dictates of enlightened reason, that the apparent diurnal movements of the stars are the *real* motions with which these bodies are impelled.—For, in the first place, *such motions are altogether unnecessary* to produce the effect intended, namely, the alternate succession of day and night with respect to our globe; and we know that the Almighty does nothing in vain, but employs the most simple means to accomplish the most astonishing and important ends. The succession of day and night can be accomplished by a simple rotation of the earth from west to east every twenty-four hours, which will completely account for the apparent motion of the heavens, in the same time, from east to west. This we find to be the case with Jupiter and Saturn, which are a thousand times larger than the earth, as well as with the other planets, which have a rotation round their axes, some in ten hours, some in twenty-three, and some in ten hours and a half; and consequently, from the surfaces of these bodies the heavens *will appear* to revolve around them in another direction from what they do to us, and, in certain instances, with a much greater degree of velocity. We must therefore conclude that our motion every day toward the east causes the heavens to appear as if they moved toward the west; just as the trees and houses on the side of a narrow river appear to move to the west when we are sailing down its current in a steamboat toward the east.

2. *Because it is impossible to conceive that so many bodies of different magnitudes, and at different distances from the earth, could all have the same period of diurnal revolution.* The sun is four hundred times farther from us than the moon, and is sixty millions of times larger. Saturn and Herschel are still further from the earth; the comets are of different sizes, and traverse the heavens in all directions and at different distances; the fixed stars are evidently placed at different distances from the earth and from each other; yet all these bodies have exactly the same period of revolution, even to a single moment, if the heavens revolve around the earth, and that, too, notwithstanding the other motions, in various directions, which many of them perform. It is, therefore, much more natural and reasonable to suppose that the earth revolves around its axis, since this circumstance solves all the phenomena and removes every difficulty.

3. Because *such a rate of motion in the heavenly bodies*, if it could be supposed to exist, *would soon shatter them to atoms.* Were a ball of wood to be projected from a cannon at the rate of a thousand miles an hour, in a few moments it would be reduced to splinters; and hence the forage and other soft substances projected from a musket or a piece of ordnance are instantly torn to pieces. What, then, might be supposed to be the consequence, were a body impelled through the regions of space with a velocity of a hundred and forty thousand millions of miles in a moment of time? It would most assuredly reduce to atoms the most compact bodies in the universe, although they were composed of substances harder than adamant. But as the fixed stars appear to be bodies of a nature somewhat similar to the sun, and as the sun is much less dense than the earth, and only a little denser than water, it is evident that they could not withstand such a rapidity of motion, which would instantly shatter their constitution, and dissipate every portion of their substance through the voids of space.

4. Because *there is no known instance in the universe* (if that to which we are now adverting be excepted) *of a larger body revolving around a smaller.* The planet Jupiter does not revolve around his satellites, which are a thousand times less than that ponderous globe, but they all revolve around him; nor does the earth, which is fifty times larger than the moon, revolve around that nocturnal luminary, but she regularly revolves about the earth, as the more immediate center of her motion. The sun does not perform his revolution around Venus or Mercury, but these planets, which are small, compared with that mighty orb, continually revolve about him as the center of their motions. Neither on earth nor in the heavens is there an instance to be found contrary to this law, which appears to pervade the whole system of universal nature; but if the diurnal revolution of the stars is to be considered as their proper motion, then the whole universe, with all the myriads of huge globes it contains, is to be considered as daily revolving around an inconsiderable ball, which, when compared with these luminaries, is only as an atom to the sun, or as the smallest particle of vapor to the vast ocean.

5. The apparent motion of the heavens cannot be admitted as *real, because it would confound all our ideas of the intelligence of the Deity.* While it tended to exalt our conceptions of his omnipotence to the highest pitch, it would convey to us a most unworthy and distorted idea of his *wisdom.* Wisdom is that perfection of an intelligent agent which enables him to proportionate one thing to another, and to devise the most proper *means* in order to accomplish important *ends.* We infer that an artist is a wise man from the nature of his workmanship, and the methods he employs to accomplish his purposes. We should reckon that person foolish in the extreme who should construct, at a great expense, a huge and clumsy piece of machinery for carrying round a grate, and the wall of a house to which it is attached, for the purpose of roasting a small fowl placed in the center of its motion, instead of making the fowl turn round its different sides to the fire. We should consider it as the most preposterous project that was ever devised were a community to attempt, by machinery, to make a town and its harbor move forward to meet every boat and small vessel that entered the river on which it was situated, instead of allowing such vehicles to move onward as they do at present. But none of these schemes would be half so preposterous as to suppose that the vast universe moves daily round an inconsiderable ball, when no end is accomplished by such a revolution but what may be effected in the most simple manner. Such a device, therefore, cannot be any part of the arrangements of Infinite Wisdom. It would tend to lessen our ideas of the *intelligence* of that adorable Being who is "wonderful in counsel and excellent in working,"

who "established the world by his wisdom, and stretched out the heavens by his understanding," and whose wisdom as far excels that of man as the "heaven in its hight surpasses the earth."—This argument alone I consider as demonstrative of the position we are now attempting to support.

The above are a few arguments which, when properly weighed, ought to carry conviction to the mind of every rational inquirer, that the general motion which appears in the starry heavens is not real, but is caused by the rotation of the earth round its axis every day, by which we and all the inhabitants of the globe are carried round in a regular and uniform motion from west to east. When this conclusion is admitted, it removes every difficulty and every disproportion which at first appeared in the motions and arrangements of the celestial orbs, and reduces the system of the universe to a scene of beauty, harmony and order worthy of the infinite wisdom of Him who formed the plan of the mighty fabric, and who settled "the ordinances of heaven." Instead, then, of remaining in a state of absolute rest, as we are at first apt to imagine, we are transported every moment toward the east with a motion ten times more rapid than has ever been effected by steam-carriages or air-balloons. It is true, we do not feel this motion, because it is smooth and uniform, and is never interrupted. The earth is carried forward in its course, not like a ship in the midst of a tempestuous ocean, but through a smooth ethereal sea, where all is calm and serene, and where no commotions to disturb its motion ever arise. Carried along with a velocity which is common to everything around us, we are in a state somewhat similar to that of a person in a ship which is sailing with rapidity in a smooth current; he feels no motion except when a large wave or other body happens to dash against the vessel; he fancies himself at rest, while the shore, the buildings, and the hills appear to him to move; but the smallness of the vessel, compared with the largeness of the objects which seem to move, convinces him that the motion is connected with the ship in which he sails: and on similar principles we infer that the apparent motion of the heavens is caused by the real motion of the earth, which carries us along with it as a ship carries its passengers along the sea. With regard to motion, it may be observed, that, strictly speaking, we do not *perceive* any motion either in the earth or in the heavens. When we look at a star with the utmost steadiness, we perceive no motion, although we keep our eye fixed upon it for a few minutes; but, if we mark the position of the star with regard to a tree or a chimney top, and, after an hour or two, view the star from the same station, we shall find that it then appears in a different direction. Hence we infer that motion has taken place; but whether the motion be in the star or in the persons who have been observing it, remains still to be determined. We perceive no motion in the star any more than we feel the motion of the earth. All that we perceive is, that the two objects have changed their relative positions; and, therefore, the body that is really in motion must be determined by such considerations as we have stated above.

Beside the apparent diurnal revolution of the heavens, there is another apparent motion which requires to be considered. It is well known to every one who has paid the least attention to this subject, that we do not perceive the same clusters of stars at every season of the year. If, for example, we take a view of the starry heavens on the first of October, at ten o'clock in the evening, and again, at the same hour, on the first of April, we shall find that the clusters of stars in the southern parts of the heavens are, at the latter period, altogether different from those which appeared in the former; and those which are in the neighborhood of the pole will appear in a different position in April from what they did at the same hour in the month of October. The square of the *Great Bear*, for example, will appear immediately *below* the pole-star in October; whereas in April it will appear as far *above* it, and near to the zenith. In the former case, the two stars called the *Pointers* will point *upward* to the pole, in the latter case they will point *downward*. In October this constellation will appear nearly in the position represented in fig. 1 (p. 13); in April it will appear nearly as represented in fig. 3 (p. 13). These variations in the appearance of the stars lead us to conclude that there is an *apparent annual motion* in these luminaries. This motion may be observed, if we take notice, for a few days or weeks, of those stars which are situated near the path of the sun When we see a bright star near the western horizon, a little elevated above the place where the sun went down, if we continue our observation we shall find that every day it appears less elevated at the same hour, and seems to be gradually approaching to the point of the heavens in which the sun is situated, until, in the course of a week or two, it ceases to be visible, being overpowered by the superior brightness of the sun. In the course of a month or two the same star which disappeared in the west will be seen rising some time before the sun in the east, having passed from the eastern side of the sun to a distance considerably westward of him. The stars in the western quarter of the heavens which appeared more elevated will be found gradually to approximate to the sun, until they likewise disappear; and in this manner all the stars of heaven seem to have a revolution, distinct from their diurnal, from east to west, which is accomplished in the course of a year.

The different positions of the *Pleiades*, or seven stars, at different seasons of the year, will afford every observer an opportunity of perceiving this motion. About the middle of September these stars will be seen, about eight o'clock in the evening, a little to the south of the north-east point of the horizon; about the middle of January, *at the same hour*, they will be seen on the meridian, or due south; on the first of March they will be seen half-way between the zenith and the western horizon; about the middle of April they will appear very near the horizon; soon after which they will be overpowered by the solar rays, and will remain invisible for nearly two months, after which they will re-appear in the east, early in the morning, before the rising sun.

This annual motion of the stars evidently indicates that the sun has an *apparent* motion every day from *west* to *east*, contrary to his apparent diurnal motion, which is from east to west. This apparent motion is at the rate of nearly a *degree* every day, a space nearly equal to twice the sun apparent diameter. In this way the sun appears to describe a circle around the whole heavens, from west to east, in the course of a year. This apparent motion of the sun is caused by the *annual* revolution of the earth around the sun as the center of its motion, which completely accounts for all the apparent movements in the sun and stars to which we have now adverted. If we place a candle upon a table in the midst of a room, and walk round it in a circle, and, as we proceed, mark the different parts of the opposite walls with which the candle appears coincident, when we have completed our circle the candle will appear to have made a revolution round the room. If the walls be conceived to represent the starry heavens, and the candle the sun, it will convey a rude idea of the apparent motion of the sun, and the different clusters of stars which appear at different seasons of the year in consequence of the annual motion of the earth. But this subject will be more particularly explained in the sequel.

From what we have now stated in relation to the apparent motions of the heavens, we are necessarily led to conceive of the earth as a body, placed, as it were, in the midst of infinite space, and surrounded in every direction, above, below, on the right hand and on the left, with the luminaries of heaven, which display their radiance from every quarter at immeasurable distances; and that its annual and diurnal motions account for all the movements which appear in the celestial sphere. Hence it is a necessary conclusion, that we are surrounded at all times with a host of stars, in the *day-time* as well as in the night, although they are then imperceptible. The reason why they are invisible during the day is obviously that their fainter light is overpowered by the more vivid splendor of the sun and the reflective power of the atmosphere. But although they are then imperceptible to the unassisted eye, they can be distinctly perceived, not only in the mornings and evenings, but even at noonday, while the sun is shining bright, by means of telescopes adapted to an equatorial motion; and in this way almost every star visible to the naked eye at night can be pointed out, even amid the effulgence of day, when it is within the boundary of our hemisphere. When the stars which appear in our sky at night have, in consequence of the rotation of the earth, passed from our view, in about twelve hours afterward they will make their appearance nearly in the same manner to those who live on the opposite side of the globe; and when they have cheered the inhabitants of those places with their radiance, they will again return to adorn our nocturnal sky.

On the whole, *the starry heavens present, even to the vulgar eye, a scene of grandeur and magnificence.* We know not the particular destination of each of those luminous globes which emit their radiance to us from afar, or the specific ends it is intended to subserve in the station which it occupies, though we cannot doubt that all of them answer purposes in the Creator's plan worthy of his perfections and of their magnitude and grandeur; but we are certain that they have, at least, a remote relation to man, as well as to other beings far removed from us, in the decorations they throw around his earthly mansion. They serve as a glorious ceiling to his habitation. Like so many thousand sparkling lusters, they are hung up in the magnificent canopy which covers his abode. He perceives them shining and glittering on every hand, and the dark azure which surrounds them contributes to augment their splendor. The variety of luster which appears in every star, from those of the sixth magnitude to those of the first, and the multifarious figures of the different constellations, present a scene as diversified as it is brilliant. What are all the decorations of a Vauxhall Garden, with its thousands of variegated lamps, compared with ten thousands of suns, diffusing their beams over our habitation from regions of space immeasurably distant? A mere gewgaw in comparison; and yet there are thousands who eagerly flock to those gaudy shows who have never spent an hour in contemplating the glories of the firmament, which may be beheld "without money and without price." That man who has never looked up with serious attention to the motions and arrangements of the heavenly orbs must be inspired with but a slender degree of reverence for the Almighty Creator, and devoid of taste for enjoying the beautiful and the sublime.

The stars not only adorn the roof of our sublunary mansion, but they are also, in many respects, *useful* to man. Their influences are placid and gentle. Their rays, being dispersed through spaces so vast and immense, are entirely destitute of heat by the time they arrive at our abode; so that we enjoy the view of a more numerous assemblage of luminous globes without any danger of their destroying the coolness of the night or the quiet of our repose. They serve to guide the traveler both by sea and land; they direct the navigator in tracing his course from one continent to another through the pathless ocean. They serve "for signs and for seasons, and for days and years." They direct the labors of the husbandman, and determine the return and conclusion of the season. They serve as a magnificent "timepiece" to determine the true length of the day and of the year, and to mark with accuracy all their subordinate divisions. They assist us in our commerce, and in endeavoring to propagate religion among the nations, by showing us our path to every region of the earth. They have enabled us to measure the circumference of the globe, to ascertain the *density* of the materials of which it is composed, and to determine the exact position of all places upon its surface. They cheer the long nights of several months in the polar regions, which would otherwise be overspread with impenetrable darkness. Above all, they open a prospect into the regions of other worlds, and tend to amplify our views of that Almighty Being who brought them into existence by his power, and "whose kingdom ruleth over all." In these arrangements of the stars in reference to our globe, the Divine wisdom and goodness may be clearly perceived. We enjoy all the advantages to which we have alluded as much as if the stars had been created solely for the use of our world, while, at the same time, they serve to diversify the nocturnal sky of other planets, and to diffuse their light and influence over ten thousands of other worlds with which they are more immediately connected; so that, in this respect, as well as in every other, the Almighty produces the most sublime and diversified effects by means the most simple and economical, and renders every part of the universe subservient to another, and to the good of the whole.

Before proceeding further, it may be expedient to explain the *measures* by which astronomers estimate the apparent distances between any two points of the heavens. Every circle is supposed to be divided into 360 equal parts. A circle which surrounds the concavity of the heavens, as that which surrounds an artificial globe, is divided into the same number of parts. The number 360 is entirely arbitrary, and any other number, had mathematicians chosen, might have been fixed upon: and hence the French, in their measures of the circle, divide it into 400 equal parts or degrees; each degree into 100 minutes, and each minute into 100 seconds. The reason why the number 360 appears to have been selected, is, that this number may be divided into halves, quarters, and eighths, without a fraction; and, perhaps, because the year was, in former times, supposed to contain about 360 days. Each degree is divided into sixty minutes, each minute into sixty seconds, each second into sixty thirds, &c. Degrees are marked thus, °; minute, ′; seconds, ″; thirds, ‴. Thus the obliquity of the ecliptic for January 1st, 1836, was twenty-three degrees, twenty-seven minutes, forty-two seconds, which are thus expressed, 23° 27′ 42″.

It may not be improper to remark, that when we state the number of degrees between two objects, either on the earth or in the heavens, it is not intended to express the *real* distance, but only the *relative* or *apparent* distance of the objects. Thus, when we say that two places on the earth, which lie directly north and south of each other, are twenty degrees distant, it does not convey an idea of the *actual distance* of these places from each other, but only what proportion of the earth's circumference intervenes between them. If, however, we know the number of yards or miles contained in that circumference, or in a single degree of it, we can then find the actual distance, by multiplying the number of degrees by the number of miles in a degree. But this supposes that the extent of a degree on the earth's surface has been measured, and the number of yards or miles it contains ascertained. In like manner, when we say that two stars in the heavens are fifteen degrees from each other, this merely expresses their relative position, or what portion of a great circle of the celestial sphere intervenes between them, but determines nothing as to their real distance, which is far surpassing our comprehension. The real magnitude of objects or spaces in the heavens depends upon their distance. Thus, the apparent breadth or diameter of the moon is about half a degree, or nearly thirty-two minutes, and that of the sun nearly the same; but as the moon is much nearer to us than the sun, *a minute of a degree* on her surface is equal only to about seventy miles, while a minute on the sun's surface is equal to more than 28,000 miles, which is four hundred times greater. The greatest apparent diameter of Saturn is twenty seconds, or one-third of a minute; the greatest diameter of Venus is fifty-eight seconds, or nearly a minute; but as Saturn is much farther from us than Venus, his real diameter is 79,000 miles, while that of Venus is only 7,700. Before the real diameter of any object in the heavens can be determined, its distance must be first ascertained.

Those who have never been in the practice of applying angular instruments to the heavens may acquire a tolerably correct idea of the extent of space which is expressed by any number of degrees by considering that the apparent diameters of the sun and moon are about *half a degree;* that the distance between the two pointers in the Great Bear is about five degrees; that the distance between the pole-star and the nearest pointer is twenty-nine degrees; that the distance between the *Pleiades* and the ruddy star *Aldebaran*, which lies to the eastward of these stars, is fourteen degrees; that the distance between *Castor* and *Pollux* is five degrees; and the distance between *Bellatrix* and *Betelguese*, the stars in the right and left shoulder of *Orion*, is eight degrees. Perhaps the most definite measure for a common observer is that which is to be found in the three stars in a straight line which form the *belt* of Orion, which are known to every one, and which are distinguished in England by the name of the *Three Kings*, or the *Ell* and *Yard*, and in Scotland by "*The Lady's Elwand.*" The line which unites these three stars measures exactly three degrees, and, consequently, there is just one and a half degree between the central star and the one on each side of it. By applying this rule or yard to any of the spaces of the firmament, the number of degrees which intervenes between any two objects may be nearly ascertained. Orion is the most striking and splendid of all the constellations; and as the equator runs through the middle of it, it is visible from all the habitable parts of the globe. About the middle of January it is nearly due south at nine o'clock in the evening.

I have been somewhat particular in the above sketches of the apparent motions and phenomena of the heavens, because such descriptions are seldom or never given in elementary treatises; because I wish every lover of the science of astronomy to contemplate with his own eyes the scenery of the sky; and because such views and observations of the general aspect of the heavens are necessary in order to understand the true system of the universe.

CHAPTER II.

ON THE GENERAL ARRANGEMENT OF THE PLANETARY SYSTEM.

When we take an attentive view of the nocturnal heavens at different periods, we find that the stars never shift their positions with respect to each other. The stars, for instance, that form the constellation of Orion, preserve the same relative positions to each other every succeeding day, and month, and year. They exhibit the same general figure which they presented in the days of our fathers, and even in the times of Amos and of Job. We never see the three stars in the belt, which Job calls "the bands of Orion," move nearer to, or farther from, each other We never see the pointers in the Great Bear directed on any other line than toward the pole-star, nor do we see *Aldebaran* to the north or south, or to the west, of the seven stars; and the same may be said, with two or three exceptions, in regard to all the stars in the heavens, which preserve invariably the same general relations to each other from one year and century to another. Hence they have been denominated *fixed stars.* But when an attentive observer surveys the heavens with minuteness, he will occasionally perceive some bodies that shift their positions. When the movements of these bodies are carefully marked, they will be found to direct their course sometimes to the east, at other times to the west, and at certain times to remain in a fixed position; but on the whole, their motion is generally from west to east. Their motion is perceived by their appearing sometimes on one side of a star and sometimes on another. They appear to partake of the general diurnal motion of the heavens, and rise and set with the stars to which they are adjacent. These bodies have received the name of *planets*, that is, *wandering stars;* and, indeed, were their real motions such as they appear to a common observer, the name would be exceedingly appropriate. For their apparent motions are, in many instances, exceedingly irregular; and, were they delineated on paper, or attempted to be exhibited by machinery, they would appear an almost inextricable maze. Ten bodies of this description have been discovered in the heavens, five of which are invisible to the naked eye, and can only be perceived by means of telescopes. They were, of course, unknown to the ancients. The names of the five which have been known in all ages are, Mercury, Venus, Mars, Jupiter, and Saturn. The names of the other five, which have been discovered within the last sixty years, are, Vesta, Juno, Ceres, Pallas, and Uranus, or Herschel.

It was long before the true magnitudes and real motions of these globes were fully ascertained.—Most of the ancient astronomers supposed that the earth was a quiescent body in the center of the universe, and that the planets revolved around it in so many different heavens, which were nearly concentric, and raised one above another in a certain order. The first or lowest sphere was the *Moon*, then *Mercury*, and, next in order, *Venus*, the *Sun*, *Mars*, *Jupiter*, *Saturn*, and then the sphere of the fixed stars. They found it no easy matter to reconcile the daily motion, which carries the stars from east to west, with another peculiar and slow motion, which carries them round the poles of the ecliptic, and from west to east, in the period of 25,000 years; and, at the same time, with a third motion, which carries them along from east to west in a year, around the poles of the ecliptic. They were no less at a loss how to reconcile the *annual* and *daily* motions of the sun, which are directly contrary to each other.—An additional difficulty was found in the particular course pursued by each individual planet. It required no little ingenuity to invent celestial machinery to account for all the variety of motions which appeared among the heavenly orbs. After the first *mobiles*, or powers of motion, they placed some very large heavens of solid crystal, which, by rolling one over another, and by a mutual and violent clashing, communicated to each other the universal motion received from the *primum mobile*, or first mover; while, by a contrary motion, they resisted this general impression, and, by degrees, carried away, each after its own manner, the planet for the service of which it was designed.—These heavens were conceived to be *solid;* otherwise the upper ones could have had no influence on the lower to make them perform their daily motion, and they behooved to be of the *finest crystal*, because the light of the stars could not otherwise penetrate the thickness of these arches applied one over another, nor reach our eyes. Above the sphere of the fixed stars were placed the first and second crystalline heavens, and above these the *primum mobile*, which carried round all the subordinate spheres. They imagined that the *primum mobile* was circumscribed by the empyreal heaven, of a cubic form, which they supposed to be the blessed abode of departed souls. Some astronomers were contented with seven or eight different spheres, while others imagined no less than seventy of them wrapped up one within another, and all in separate motions. They no sooner discovered some new motion or effect, formerly unknown, than they immediately set to work and patched up a new sphere, giving it such motions and directions as were deemed requisite. Cycles, epicycles, deferents, centric and eccentric circles, solid spheres, and other celestial machinery, were all employed to solve the intricate motions of the heavens, which seemed to baffle all the efforts of human ingenuity. After their system was supposed to be completed, new anomalies were detected, which required new pieces of machinery to be applied to solve appearances. But after all the ingenuity displayed in their patchings and repatchings, the celestial spheres could never be got to move onward in harmony, and in accordance with the phenomena of the heavens.*

It would be no easy task to describe how their epicycles could be made to move through the thick crusts of crystal of which their spheres were made. They, however, found some means or other to extricate themselves from every difficulty, as they always had recourse to geometrical lines, which never found any obstacle to their passage on paper. To make all the pieces of their machinery move with as much smoothness and as little inconsistency as possible, they were forced to delineate certain furrows, or to notch on the arches certain grooves, in which they jointed and made the tenons and mortises of their epicycles to slide. All this celestial joiner's work, to which succeeding astronomers added several pieces to produce balancings, or perpetual goings backward and forward, had no other tendency than to conceal the sublime and beautiful simplicity of nature, and to prevent mankind, for many ages, from recognizing the true system of the world.—With all their cumbrous and complicated machinery, they never could account for the motions and other phenomena of Mercury and Venus, and the different apparent magnitudes which the planets present in different parts of their orbits.—Without admitting the motion of the earth, it would surpass the wisdom of an angel, on any rational principles, to solve the phenomena of the heavens. This is the system which has been denominated the *Ptolemaic*, from Ptolemy, an astronomer of Egypt, who first gave a particular explanation of its details; but it is understood to have been received by the ancient Greek philosophers except the Pythagoreans. It was supported by Aristotle, who wrote against the motion of the earth; and as the authority of this philosopher was thought sufficient to establish the opinion of the earth being a quiescent body, it was generally received by the learned in Europe until the sixteenth century, or a little after the period of the Reformation. This is the system to which almost all our theological writers, even of the seventeenth century, uniformly refer, when alluding to the heavenly bodies and to the general frame of the world; and, in consequence of admitting so absurd and untenable a theory, their reflections and remarks in reference to the objects of the visible world, and many of their comments on Scripture, are frequently injudicious and puerile, and, in many instances, worse than useless. That such a clumsy and bungling system was so long in vogue, is a disgrace to the ages in which it prevailed, and shows that even the learned were more prone to frame hypotheses and to submit to the authority of Aristotle, than to follow the path of observation, and to contemplate with their own eyes the phenomena of the universe. To suppose that the Architect of nature was the author of such a complex and clumsy piece of machinery, was little short of a libel on his perfections, and a virtual denial of his infinite wisdom and intelligence

---

* See La Pluche's "*Spectacle De la Nature.*"

> "Oh how unlike the complex works of man,
> Heaven's easy, artless, unencumber'd plan!"

From this brief sketch of the Ptolemaic system, we may learn into how many absurdities we involve ourselves by the denial of a single important fact and the admission of a single false principle; and the importance of substantiating every fact and proving every principle in all our investigations of the system of nature and the order of the universe.

The first among the moderns who had the boldness to assail the ancient system which had so long prevailed, was the famous *Nicolaus Copernicus*, who was born at Thorn, in Polish Prussia, in 1472, and died at Worms, where he had been made a canon of the church by his mother's brother, who was bishop of that place. His attention was early directed to the sciences of mathematics and astronomy. Having traveled into Italy for the purpose of enlarging his knowledge on such subjects, he remained some time at Bologna with Dominicus Maria, an eminent professor of astronomy, and afterward went to Rome, where he soon acquired so great a reputation that he was chosen professor of mathematics, which he taught for a long time with great applause. At the same time he was unwearied in making celestial observations. Returning to his own country, he began to apply his vast knowledge in mathematics to correct the system of astronomy which then prevailed. Having applied himself with assiduity to the study of the heavens, he soon perceived that the hypothesis of the ancient astronomers was conformable neither to harmony, uniformity, nor reason. With a bold independent spirit, and a daring hand, he dashed the crystalline spheres of Ptolemy to pieces, swept away his cycles, epicycles, and deferents, stopped the rapid whirl of the primum mobile, fixed the sun in the center of the planetary orbs, removed the earth from its quiescent state, and set it in motion through the ethereal void along with the other planets, and thus introduced simplicity and harmony into the system of the universe. But such a bold attack on ancient systems, which had been so long venerated, could not be made without danger. Even the learned set themselves in opposition to such bold innovations in philosophy; the vulgar considered such doctrines as chimeras, contrary to the evidence of the senses, and allied to the ravings of a maniac; and the church thundered its anathemas against all such opinions as most dangerous heresies. When only about thirty-five years of age, Copernicus wrote his book "On the Revolution of the Celestial Orbs;" but, fearing the obloquy and persecution to which his opinions might expose him, he withheld its publication, and communicated his views only to a few friends. For more than thirty years he postponed the publishing of this celebrated work, in which his system is demonstrated; and it was with the utmost difficulty, even in the latter part of his life, that he could be prevailed upon to usher it into the world. Overcome, at length, by the importunity of his friends, he put the work in order, and dedicated it to Pope Paul III; in which dedication, not to shock received prejudices, he presented his system under the form of a hypothesis. "Astronomers," said he "being permitted to imagine circles to explain the motion of the stars, I thought myself equally entitled to examine if the supposition of the motion of the earth would render the theory of these appearances more exact and simple."—The work was printed at Nuremberg at the expense of his friends, who wrote a preface to it, in order to palliate as much as possible, so extraordinary an innovation. But its immortal author did not live to behold the success of his work. He was attacked by a bloody flux, which was succeeded by a palsy in his left side; and only a few hours before he breathed his last he received a copy of his work, which had been sent to him by one of his scientific friends. But he had then other cares upon his mind, and composedly resigned his soul to God on the 23d of May, 1543, in the seventy-first year of his age. His remains were deposited in the cathedral of Frauenberg; and spheres cut in relief on his tomb were the only epitaph that recorded his labors. Not many years ago his bones were wantonly carried off to gratify the impious curiosity of two Polish travelers.*

The system broached by Copernicus, notwithstanding much opposition, soon made its way among the learned in Europe. It was afterward powerfully supported by the observations and reasonings of Galileo, Kepler, Halley, Newton, La Place, and other celebrated philosophers, and now rests on a foundation firm and immutable as the laws of the universe. The introduction of this system may be considered an era as important in philosophy as that of the Reformation was in politics and religion. It had even a bearing upon the progress of religion itself, and upon the views we ought to take of the character and operations of the Creator. It paved the way for a rational contemplation of his works, and for all those brilliant discoveries in the celestial regions which have expanded our views of his adorable perfections, and of the boundless extent of his universal empire. It was promulgated nearly at the same period when the superstitions of the dark ages were beginning to be dissipated; when the power of the Romish church had lost its ascendency; when the art of printing had begun to illuminate the world; when the mariner's compass was applied to the art of navigation; when the western continent was discovered by Columbus; and when knowledge was beginning to diffuse its benign influence over the nations; and, therefore, it may be considered as connected with that series of events which are destined, in the moral Government of God, to enlighten and renovate the world.

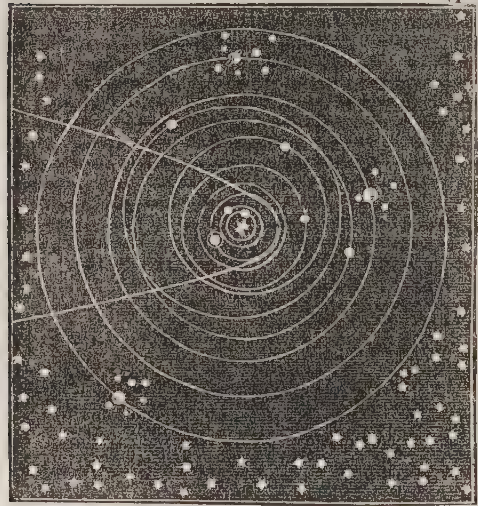
I shall now proceed to consider the arrangement of the planetary or Copernican system, and some of the arguments by which it is supported.

In this system the sun is considered as placed near the center. Around this central luminary the planets perform their revolutions in the following order:—First, the planet Mercury, at the distance from the sun's center of about 37 millions of miles. Next to Mercury is Venus, distinguished by the name of the morning and evening star, at the distance of 31 millions of miles from the orbit of Mercury, and 68 millions from the sun. The Earth is considered as the planet next in order, which revolves at the distance of 95 millions of miles from the sun, and 27 millions from the orbit of Venus. Farther from the sun than the Earth is the planet Mars, which is 145 millions of miles from the sun, and 50 millions beyond the orbit of the Earth. Next to the orbit of Mars are four small planetary bodies, sometimes named *Asteroids*, which were discovered at different times about the beginning of the present century. They are named Vesta, Juno, Ceres, and Pallas. Of these, the first in order from the sun is Vesta, at the distance of 225 millions of miles; the next, Juno, at the distance of 253 millions. Ceres, at 260 millions; and Pallas, at 266 millions of miles. The planet Jupiter is the next in order, and performs its revolution in an orbit 495 millions of miles from the sun, and 400 from the orbit of the earth. Saturn is nearly double the distance of Jupiter from the sun, being distant from that orb above 900 millions of miles. The most distant planet in the system which has yet been discovered is Uranus, or Herschel, which is removed from the sun at more than double the distance of Saturn; namely, above 1800 millions of miles. The orbit of this planet includes the orbits of the whole of the bodies of the solar system that have hitherto been discovered, and is eleven thousand three hundred millions of miles in circumference, and three thousand six hundred millions in diameter. To move round this circumference at the rate of thirty miles every hour would require above forty-two thousand nine hundred years. Such is the order, and such are the ample dimensions of that system of which we form a part; and yet it is but a mere speck in the map of the universe. The following diagram exhibits the order of the planets in the solar system.

---

* A *fac-simile* of one of the letters of Copernicus may be seen in No. IX of the "Edinburgh Philosophical Journal," for July, 1821; and an engraving of the house in which he lived in No. XIII of the same Journal for July, 1822.

Fig. 5.



In the foregoing figure the small central star represents the sun, and the circles represent the orbits of Mercury, Venus, the Earth, Mars, Vesta, Juno, Ceres, Pallas, Jupiter, Saturn, and Uranus, in the order here enumerated. The orbits of the new planets, Vesta, Juno, Ceres, and Pallas, are represented as crossing each other, as they do in nature; and the portion of a long ellipse which crosses the orbits of all the planets represents the orbit of a comet. The *proportional distances* and *magnitudes* of the planets are represented in a subsequent chapter.

I shall now proceed to offer a few arguments or demonstrations of the truth of the solar system, as first proposed by Copernicus, and now received by all astronomers. I shall first state those which may be called presumptive arguments, or which amount to a high degree of probability, and then briefly illustrate those which I consider as demonstrative. Having already endeavored to prove the diurnal rotation of the earth, I shall consider that point as settled, and confine myself, at present, to the consideration of the earth's *annual revolution*, and the phenomena of the planets which result from this motion.

The presumptive arguments that the earth is a planetary body, and revolves round the sun in concert with other planets, are, 1. *It is most simple and agreeable to the general arrangements of the Creator* that such an order as we have now stated should exist in the planetary system. For, by the motion of the earth, all the phenomena of the heavens are resolved and completely accounted for, which they cannot be on any other system, without the supposition of clumsy and complex machinery and motions altogether repugnant to reason and to what we know of the other operations of the all-wise Creator. Beside, it is contrary to the first rule laid down in philosophy,—"That more causes of natural things are not to be admitted than are both true and sufficient to explain the phenomena." But the Ptolemaic, or vulgar system of the world, assumes the existence of facts which can never be established, and introduces cumbrous and complicated motions which are quite unnecessary for explaining the phenomena. 2. Because *it is more rational to suppose that the earth moves about the sun, than that the huge masses of the planets*, some of which are a thousand times larger than our globe—or that the stupendous body of the sun, which is thirteen hundred thousand times greater—*should perform a revolution around so comparatively small a globe as the earth.* To suppose the contrary, would be repugnant to all the laws of motion that are known to exist in the universe. We might as well expect that a sling, which contains a millstone in it, may be fastened to a pebble, and continue its motion about that pebble without removing it, as that the sun can revolve about the earth while the earth continues immovable in the center of that motion.

3. It was a law discovered by Kepler, by which all the planets, both primary and secondary, are regulated, "That the squares of the periodic times of the planets' revolutions are as the cubes of their distances;"* but, if the sun move around the earth, that law, which is established on the most accurate observations, is completely destroyed, and the general order and symmetry of the system of nature are infringed upon and interrupted. For, according to that law, the sun would be so far from revolving about the earth in 365 days, that it would require no less than 589 years to accomplish one revolution, as will appear from the following calculation: The moon revolves round the earth in twenty-seven days eight hours, at the distance of 240,000 miles; the sun is placed at the distance of 95,000,000 miles. The period of the revolution of any body revolving at that distance will be found, according to the law now stated, by the following proportion: As the cube of the moon's distance : is to the cube of the sun's distance : : so is the square of the moon's period ; to the square of the period of any body moving about the earth at the distance of the sun. Now, the cube of the moon's distance, 240,000, is 13,-

---

* For example; if one planet were four times as distant as another, it would revolve in a period eight times as long; for the cube of 4=64 is equal to the square of 8. Thus Mars is about four times as remote from the sun as Mercury, and Uranus four times as remote as Jupiter, and their periods of revolution correspond to this proportion of their distances. This argument, when properly understood, is demonstrative.

824,000,000,000,000; the cube of the sun's distance, 95,000,000, is 857,375,000,000,000,000,000,000. The square of the moon's periodical time, twenty-seven days eight hours, is 747, which, multiplied by the cube of the sun's distance, and divided by the cube of the moon's distance, is 46,329,508,463, the square root of which is 215,242 days, or 589 years and 257 days. This calculation is of itself sufficient to determine the point in question, for there is no exception known to the law we have stated. Beside, did the sun observe this universal law, and yet revolve in 365 days, his distance ought to be only about 1,351,000 miles, whereas it can be shown that it is about 95,000,000. For, as the square of the moon's period, 747 : is to the square of the sun's, 365×365=133,225 : : so is the cube of the moon's distance from the earth 13,824,000,000,000,000 : to 2,465,465,050,240,963,855, the cube root of which is 1,351,295, or one million, three hundred and fifty-one thousand, two hundred and ninety-five miles, which should be the sun's distance if he revolved about the earth in accordance with this universal law, which governs every moving body, both primary and secondary.*

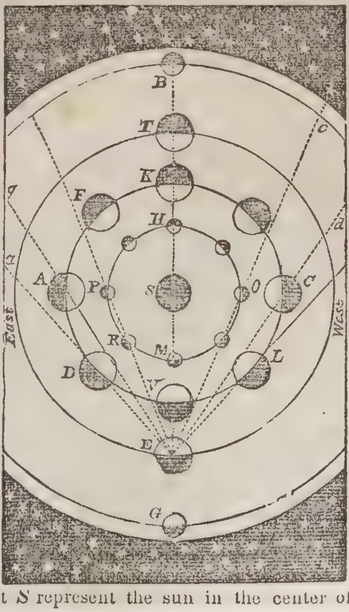
4. It appears most reasonable to conclude that the sun is placed near the center of the planetary system, as it is the fountain of light and heat for cheering and irradiating all the worlds within the sphere of its influence; and it is from the center alone that these emanations can be distributed in uniform and equable proportions to all the planets. If the earth were in the center, with the sun and planets revolving around it, the planetary worlds would be, at different times, at very different distances from the sun; and, when nearest to him, would be scorched with excessive heat, and at their greatest distance would be frozen with excessive cold; and as some of the planets would, on this supposition, be sometimes five times the distance from the source of light and heat which they are at other times, it would produce the same effect as if the earth were occasionally to be carried beyond the orbit of Jupiter, four hundred and seventy millions of miles from its present position. But if the sun be considered as placed in the center of the system, we have then presented to our view a system of universal harmony and order: the planets all revolving around the great central orb by the universal law or power of gravitation, and everything corresponding to the laws of circular motion and central forces; otherwise we are left entirely in the dark as to the operations of nature and the system of the universe.

There is no more difficulty in conceiving the earth to move than that it should remain quiescent in the same place. For if the earth remain at rest in the center of the system, it is supported upon nothing, in the midst of infinite space, by the power of Omnipotence: and we have as little conception how a ponderous globe of the size of the earth should remain suspended upon *nothing*, as that it should move through the voids of space with a velocity of sixty-eight thousand miles an hour. The Power that is able to suspend it in empty space can as easily make it fly through the ethereal regions, as is the case with Jupiter and Saturn, which are globes a thousand times larger; and such a motion is *necessary* in order to display the harmony and proportion of the Creator's works, and to vindicate his all-perfect wisdom and intelligence. It is even no more difficult to conceive such a motion than it is to conceive how the earth can be inhabited all round, and that there can be no such thing as *up* or *down* in the universe, absolutely considered; how, for example, persons can stand upright on the opposite sides of the globe; that our antipodes, standing with their heads in an opposite direction to ours can look *up* into the sky and *down* to the earth just as we do, without any more danger of falling off from its surface than we are of being carried upward into the air. These are circumstances which necessarily flow from the rotundity of the earth and its attractive power; they are known to every one, and cannot possibly be disputed, unless we deny the globular form of the earth, or, in other words, contradict the evidence both of our reason and our senses. But we know as little of that power which draws everything to the earth on all sides, as we do of a power which carries a planet round its orbit at the rate of a hundred thousand miles an hour. Both are effects of that Almighty agent who contrived the universe, "who is wonderful in counsel and excellent in working," and "whose ways," in numerous instances, "are past finding out." But, in all cases where the least doubt exists, we ought to adopt that view of the Creator's plans and operations which is most consistent with the ideas of a Being of infinite perfection.

The arguments now stated, although we could produce no other, would be sufficient to corroborate the idea that the earth is a planetary body, performing its motion through the depths of space; but, happily, we are able to produce proofs of the sun occupying the center of the system, which may be considered as demonstrative. These proofs I shall now state as briefly as possible.

1. In the first place, the planets Mercury and Venus are uniformly observed to have two conjunctions with the sun, but no opposition, which could not possibly happen unless the orbits of those planets lay *within* the orbit of the earth, as delineated in the plan of the solar system. This circumstance will be more particularly understood by the following diagram.

Fig. 6.



Let *S* represent the sun in the center of the system, *M*, Mercury; *V*, Venus; *E*, Earth; and *G*, Mars. It is evident that when Mercury is at *M* and Venus at *V*, they will be seen from the earth, *E*, in the same part of the heavens as the sun; namely, at *B*, where Mars is represented; because they are all situated in the same straight line, *E B*. In this position they are between the sun and the earth, and this is called their *inferior* conjunction. Again, when Mercury and Venus come to the situations *H*, *K*, they are again in the straight line joining the centers of the earth and sun, and are therefore seen in the same part of the heavens with that orb. In these last positions they are *beyond* the sun, which is now between them and the earth. This is called their *superior* conjunction. Here it is evident that these two planets must appear twice in conjunction with the sun, in each revolution, to a spectator on the earth at *E*; but they can never appear *in opposition* to the sun, or, in other words, they can never be seen in the east immediately after the sun has set in the west, as is the case with Mars, which may be seen at *G* when the sun appears at *B*, in the opposite direction; all which appearances are exactly correspondent with observation, but could never take place if the earth were the center of their motions.

---

* The primary planets are those which revolve about the sun as their center, as Venus, Mars, and Jupiter. The *secondary* planets are those which revolve around the primary, as the moons of Jupiter, Saturn, and Uranus.

2. The greatest *elongation* or distance of Mercury from the sun is twenty-nine degrees, and that of Venus about forty-seven degrees, which answers exactly to observation, and to the positions and distances assigned to them in the system; but if they moved round the earth as a center, they would sometimes be seen 180 degrees from the sun, or *in opposition* to him. But they have never been seen in such a position by any observer, either in ancient or modern times, nor at greater distances from the sun than those now specified. It is evident, from the figure, that when Venus is at *D*, the point of its greatest elongation, it will be seen at *a*, in the direction of *E a*, which forms an angle of forty-seven degrees with the line *E B*, or the direction of the sun as seen from the earth. In like manner Mercury, when at its greatest elongation, at *R*, will be seen at *e*, which forms a less angle than the former with the line of direction in which the sun is seen. Hence it is that Mercury is so rarely seen, and Venus only at certain times of the year; whereas, were the earth at rest in the center of the planetary orbits, these planets would be seen in all positions and distances from the sun in the same manner as the moon appears.

3. The planets Mars, Jupiter, Saturn, Uranus, and all the other superior planets, have each their *conjunctions* and *oppositions* to the sun, alternate and successively, which could not be unless their orbits were *exterior* to the orbit of the earth.—Thus, from the earth at *E* Mars will appear in conjunction with the sun at *B* and in opposition at *G*; that is, in a part of the heavens 180 degrees distant from the sun, or directly opposite to him; and the same is the case with all the planets beyond the orbit of Mars, which proves that they are all situated in orbits which *include* the orbit of the earth.

4. In the arrangements of the planets in the system, as formerly stated, they will all be sometimes much nearer to the earth than at other times; and, consequently, their brightness and splendor, and likewise their *apparent diameters*, will be proportionably greater at one time than at another. This corresponds with every day's observation. Thus the apparent diameter of Venus, when greatest, is fifty-eight seconds, and when least, about ten seconds; of Mars, when greatest about twenty-five seconds, and when least, not above four or five seconds; so that in one part of his orbit he is five times nearer to the earth than at the opposite part, and, consequently, appears twenty-five times larger in surface. Thus, when Mars is in the point *G*, in opposition to the sun, he is the whole diameter of the earth's orbit, or 190 millions of miles nearer us than when he is in conjunction, in the point *B*. In the one case he is only 50 millions of miles distant from the earth, while in the other he is no less than 240 millions of miles; and his apparent magnitude varies accordingly. But, according to the system which places the earth in the center, the apparent magnitude of Mars, and of all the other planets, should always be equal, in whatever points of their orbits they may be situated.

5. When the planets are viewed through good telescopes, they appear with different phases; that is, with different parts of their bodies enlightened. Thus, Mars sometimes appears round, or with a full enlightened face; and at other times he presents a gibbous phase, like that of the moon three or four days before the full. Venus presents all the different phases of the moon, appearing sometimes with a gibbous phase, sometimes like a half moon, and at other times like a slender crescent Thus, at *V*, her dark side is turned to the earth, and she is consequently invisible, unless she happens to pass across the disc of the sun, when she appears like a round black spot on the surface of that luminary. At *D* she appears like a crescent; at *A* like a half moon, because only the one-half of her enlightened side is turned toward the earth; and at *F* she presents a gibbous phase. When Copernicus first proposed his system, it was one of the strongest objections which his adversaries brought against it, and by which they supposed they had completely confuted him; namely, that "if his hypothesis were true, Venus and Mercury must vary their phases like the moon, but that they constantly appeared round." Copernicus at once admitted that these consequences were justly drawn; and he attributed the cause of their round appearances to the structure of our eyes, to the distance of the objects, and to those radiating crowns which hinder us from judging either of the size or the exact form of the stars and planets; and he is said to have prophesied that one day or other these various phases would be discovered; and little more than a half century intervened, when the telescope (which was unknown in the time of Copernicus), in the hands of Galileo, determined to a certainty the matter in dispute, and confirmed the prediction of that eminent astronomer. How great, may we suppose, would have been the transport of that illustrious man had a telescope been put into his hands, and had he seen, as we now do, that Venus, when she appears most brilliant, exhibits, in reality, the form of a crescent! so that this formidable objection to the truth of his system has now become one of the strongest and most palpable demonstrations of the reality of that arrangement which has placed the sun in the center, and set the earth in motion between Mars and Venus.

6. All the planets in their motions are seen sometimes to move *direct;* sometimes *retrograde;* and at other times to remain *stationary*, without any apparent motion: in other words, in one part of their course they appear to move to the *east;* in another part to the *west;* and at certain points of their orbits they appear fixed for some time in the same position. Thus, Venus, when she passes from her greatest elongation westward, at *L*, to her elongation eastward, at *D*, through the arc

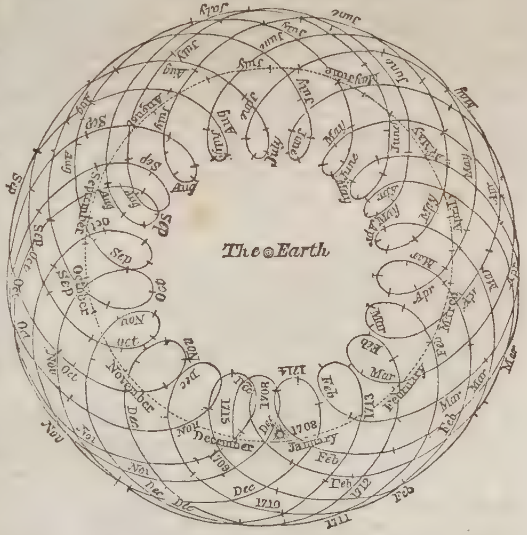
L C K F A D, will appear *direct* in motion, or from west to east; but as she passes from *D* to *L*, through the arc *D V L*, she will appear *retrograde*, or as if she were moving from east to west. When she is in those parts of her orbit most distant from the sun, as at *D* and *L*, she will appear for some time stationary, because the tangent line or visual ray appears to coincide for some time with the orbit of the planet; just as a ship at a great distance, when moving directly toward the eye in the line of vision, appears for a little time to make no progress. All these apparent diversities of motion are *necessary* results of the Copernican system, and they coincide with the most accurate observations; but they are altogether inexplicable on any other hypothesis.

7. The planets Mercury and Venus, in their superior conjunctions with the sun, as at *H* and *K*, are sometimes hid behind the sun's body; which could never happen on the Ptolemaic hypothesis, because in it the orbit of the sun is supposed to be *exterior* to the orbits of these two planets.

8. The *times* in which these conjunctions, oppositions, direct and retrograde motions, and stationary aspects of the planets happen, are not such as they would be if the earth were at rest in its orbit, but *precisely* such if the earth move, and all the other planets in the periods assigned them. Thus, suppose Venus at any time in conjunction with the sun at *V*; were the earth at rest in *E*, the next conjunction of the same kind would happen again when Venus had made just one revolution, that is, in 224 days. But this is contrary to experience; for a much longer time is found to intervene between two conjunctions of the same kind, as must be if we suppose the earth to have a motion in the same direction. For, when Venus comes to the point *V*, the earth will have passed in that time from *E* to some other part of its orbit, and from this part still keeps moving on until Venus overtakes it, and gets again between it and the sun. The period which Venus will take before she overtakes the earth and comes in conjunction with the sun, is found as follows: The daily mean motion of the earth is fifty-nine minutes eight seconds (which is the same as the *apparent* mean motion of the sun), and the daily mean motion of Venus is one degree, thirty-six minutes, eight seconds. The difference of these mean motions is thirty-seven minutes. Therefore, as 37′ : is to the number of minutes in the whole circle of 360 degrees, namely, 21600′ : : so is one day : to 583 days, 18 5-4 hours, which is the time between two conjunctions of the same kind, or one year and a little more than seven months, which is somewhat more than two and a half revolutions of Venus, and which perfectly agrees with the most accurate observations.

In the last place, if we were to suppose the earth at rest in the center of the planetary system, *the motions of all the planets would present a scene of inextricable confusion.* They would appear so irregular and anomalous that no rational being would ever suppose they could be the contrivances of an All-wise Being, possessed of every perfection. This will appear at once by casting the eye on Fig. 7, which represents the apparent motion of the planet Mercury, as seen from the earth, from the year 1708 to 1715, as originally delineated by the celebrated astronomer Cassini, and published in the Memoirs of the Royal Academy of Sciences. Here the motion of this planet appears to describe a complicated curve, or a series of loops or spirals running into each other, instead of a regular circular motion in an orbit; and such irregular curves must be the *real* motion of the planet, to account for all its appearances, if the earth were considered as remaining fixed in the center of its motion. On each side of the loops in the figure it appears stationary; in that part of the loop next the earth it appears retrograde; and in all the rest of the path, which seems to stretch far away from the earth, it appears direct, until its course again appears to run into a loop. Let the reader trace the whole of the curve here delineated, and then ask himself whether such motions can possibly be real, or the contrivances of Infinite Wisdom. The motions of Venus, and all of the superior planets, as seen from the earth, present similar curves and anomalies. Now it is a fact, that when the earth is considered as moving round the sun in a year, between the orbits of Venus and Mars, all these apparent irregularities are completely accounted for by the combination of motions produced by our continual change of position, in consequence of the earth's progress in its annual orbit; and thus the movements of all the planets are reduced to perfect harmony and order.

Fig. 7



Such is a brief summary of the leading proofs which may be brought forward to establish the fact of the annual motion of the earth round the sun. They all converge toward the same point, and hang together in perfect harmony. It is next to impossible that such a combination of arguments could be found to prove a false position. When thoroughly understood and calmly considered they are calculated to produce on the mind of every unbiassed inquirer as strong a conviction of the point in question, as if, from a fixed position in the heavens, we actually beheld the earth and all its population sweeping along through the ethereal spaces with the velocity of sixty-eight thousand miles every hour. These arguments are plain and easy to be understood if the least attention be bestowed. Most of them require nothing more than common observation, or, in other words common sense, in order to understand and appreciate them; and he who will not give himself the trouble to weigh them with attention must be contented to remain in ignorance. I have stated them with more particularity than is generally done in elementary books on this subject, because they lie at the foundation of astronomical science, and of all our views of the amplitude and order of the universe: and because many profess to believe in the motion of the earth merely on the authority of others, without examining the grounds of their belief, and, consequently, are never fully and rationally convinced of the important position to which we have adverted.

The motion of the earth presents before us *a most sublime and august object of contemplation.* We wonder at beholding a steam carriage, with all its apparatus of wagons and passengers, carried forward on a railway at the rate of thirty miles an hour, or a balloon sweeping through the atmosphere with a velocity of sixty miles in the same time. Our admiration would be raised still higher, should we behold Mount Etna, with its seventy cities, towns, and villages, and its hundred thousand inhabitants, detached from its foundations, carried aloft through the air, pouring forth torrents of red-hot lava, and impelled to the continent of America in the space of half an hour. But such an object, grand and astonishing as it would be, could convey no adequate idea of the grandeur of such a body as the earth flying through the voids of space in its course round the sun. Mount Etna, indeed, contains a mass of matter equal to more than 800 cubical miles, but the earth comprises an extent of more than 263,000,000,000 of solid miles, and, consequently, is more than three hundred millions of times larger than Etna, and of a much greater density. The comparative size of this mountain to the earth may be apprehended by conceiving three hundred millions of guineas laid in a straight line, which would extend 4700 miles, or from London to the equator, or to south America. The whole line of guineas throughout this vast extent would represent the bulk of the earth, and a single guinea, which is only about an inch in extent, would represent the size of Etna compared with that of the earth. Again: Etna, in moving from its present situation to America in half an hour, would move only at the rate of 130 miles in a minute; while the earth in its annual course flies with a velocity of more than 1130 miles in the same space of time, or about nine times that velocity.

How august, then, and overpowering the idea, that during every pulse that beats within us we are carried nearly twenty miles from that portion of absolute space we occupied before! that during the seven hours we repose in sleep, we, and all the inhabitants of the world, are transported 470,000 miles through the depths of space; that during the time it would take to read deliberately from the beginning of the last paragraph to the present sentence, we have been carried forward with the earth's motion more than 4500 miles; and that, in the course of the few minutes we spend in walking a mile, we are conveyed through a portion of absolute space to the extent of more than 18,000 miles. What an astonishing idea does such a motion convey of the ENERGIES of the Almighty Creator, especially when we consider that thousands of rolling worlds, some of them immensely larger than our globe, are impelled with similar velocities, and have, for many centuries past, been running without intermission their destined rounds! Here, then, we have a magnificent scene presented to view, far more wonderful than all the enchanted palaces rising and vanishing at the stroke of the magician's rod, or all the scenes which the human imagination has ever created, or the tales of romance have recorded, which may serve to occupy our mental contemplation when we feel *ennui*, or are at a loss for subjects of amusement or reflection. We may view in imagination this ponderous globe on which we reside, with all its load of continents islands, oceans, and its millions of population, wheeling its course through the heavens at a rate of motion, *every day*, exceeding 1,600,000 miles, we may transport ourselves to distant regions and contemplate globes far more magnificent moving with similar or even greater velocities; we may wing our flight to the starry firmament where worlds unnumbered run their ample rounds where suns revolve around suns, and systems around systems, around the throne of the Eternal; until, overpowered with the immensity of space and motion, we fall down with reverence, and worship HIM who presides over all the departments of universal nature, "who created all worlds, and for whose pleasure they are and were created."

CHAPTER III.

ON THE MAGNITUDES, MOTIONS, AND OTHER PHENOMENA OF THE BODIES CONNECTED WITH THE SOLAR SYSTEM

IN the elucidation of this subject, I shall, in the first place, present a few sketches of the magnitudes, motions, and other phenomena of the primary planets belonging to the solar system. These planets, as formerly stated, are, Mercury, Venus, Mars, Vesta, Juno, Ceres, Pallas, Jupiter, Saturn, and Uranus, which are here mentioned in the order of their distance from the sun.

In this order I shall proceed to give a few descriptions of the principal facts which have been ascertained respecting each planet.

I THE PLANET MERCURY.

This planet is the nearest to the sun of any that have yet been discovered, although a space of no less than thirty-seven millions of miles intervene between Mercury and the central luminary. Within this immense space several planets may revolve, though they may never be detected by us, on account of their proximity to the sun. To an inhabitant of Mercury, such planets, if any exist, may be as distinctly visible as Venus and

Mercury are to us; because they will appear, in certain parts of their course, at a much greater elongation from the sun than they can to us. This planet, on account of its moving in the neighborhood of the sun, is seldom noticed by a common observer. It is only to be seen by the naked eye about the period of its greatest elongation from the sun, which is sometimes only about 16° or 17°, and never exceeds 29°. These elongations happen, at an average, about six or seven times every year; about three times when the planet is eastward of the sun, and three times when it is to the westward. This planet, therefore, can only be seen by the unassisted eye for a few days about these periods, either in the morning a little before sunrise, or in the evenings a little after sunset. As it is sometimes not above 16°, even at its greatest elongation, from the point of sunrise or sunset, and is likewise very near the horizon, it is sometimes very difficult to distinguish it by the naked eye, and at all other times it is generally imperceptible without a telescope. It is said that the celebrated astronomer, Copernicus, had never an opportunity of seeing this planet during the whole course of his life. I have seen Mercury three or four times with the naked eye, and pretty frequently with a telescope. With a magnifying power of 150 times, I have seen it about the time of its greatest elongation, more than half an hour after sunrise, when it appeared like a small brilliant half moon; but no spots could be discovered upon it. To the naked eye, when it is placed in a favorable position, it appears with a brilliant white light, like that of Venus, but much smaller and less conspicuous. The best mode of detecting it is by means of an equatorial telescope, which, by a slight calculation and the help of an ephemeris, may be directed to the precise point of the heavens where it is situated. The most favorable seasons of the year for observing it are when its greatest elongations happen in the month of March or April, and in August or September. In winter it is not easily perceived, on account of its very low altitude above the horizon at sunrise and sunset; and in summer, the long twilight prevents our perception of any small object in the heavens. From the planets Saturn and Uranus, Mercury would be altogether invisible, being completely immersed in the splendor of the solar rays; so that an inhabitant of these planets would never know that such a body existed in the universe, unless he should happen to see it when it passed, like a small dark point, across the disc of the sun.

Mercury revolves around the sun in the space of eighty-seven days twenty-three hours, which is the length of its year; but the time from one conjunction to the same conjunction again, is about 116 days; for as the earth has moved about a fourth part of its revolution during this period, it requires nearly thirty days for Mercury to overtake it, so as to be in a line with the sun. During this period of about 116 days it passes through all the phases of the moon, sometimes presenting a gibbous phase, sometimes that of a half moon, and at other times the form of a crescent; which phases and other particulars will be more particularly explained in the description I shall give of the planet Venus. Mercury, at different times, makes a transit across the sun's disc; and as its dark side is then turned to the earth, it will appear like a round spot upon the face of the sun; and when it passes near the center of the sun, it will appear for the space of from five to seven hours on the surface of that orb Its last transit happened on the 7th of November, 1835, which was visible in the United States of America, but not in Britain, as the sun was set before its commencement. The next transits, to the end of the present century, are as follows·

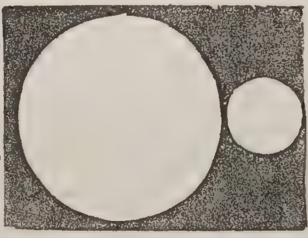
	Hours.	Minutes.	
1845, May 8th...........	7	54	P. M.
1848, November 9th.......	1	38	P. M.
1861, November 12th......	7	20	P. M.
1868, November 5th.......	6	44	A. M.
1878, May 6th............	6	38	P. M.
1881, November 8th.......	0	40	A. M.
1891, May 10th...........	2	45	A. M.
1894, November 10th......	6	17	P. M.

The time stated in the above table is the mean time of conjunction at Greenwich, or nearly the middle of the transit; so that, in whatever part of the world the sun is risen at that time, the transit will be visible if no clouds interpose. The next two transits, in 1845 and 1848, will be partly visible in Britain.

Few discoveries have been made on the surface of this planet by means of the telescope, owing to the dazzling splendor of its rays, which prevents the telescope from presenting a well-defined image of its disc; owing, likewise, to the short interval during which observations can be made, and particularly to its proximity to the horizon, and the undulating vapors through which it is then viewed. That unwearied observer of the heavens, Sir William Herschel, although he frequently viewed this planet with magnifying powers of 200 and 300 times, could perceive no spots or any other phenomenon on its disc from which any conclusions could be deduced respecting its peculiar constitution or the period of its rotation. Mr. Schroeter, an eminent German astronomer, however, appears to have been more successful. This gentleman has long been a careful observer of the phenomena of the planetary system, by means of telescopes of considerable size, and has contributed not a few interesting facts to astronomical science. He assures us that he has seen not only spots, but even mountains on the surface of Mercury, and that he succeeded in ascertaining the altitude of two of these mountains. One of them he found to be little more than 1000 toises in height, or about an English mile and 372 yards. The other measured 8900 toises, or ten miles and 1378 yards, which is more than four times higher than Mount Etna or the Peak of Teneriffe. The highest mountains are said to be situated in the southern hemisphere of this planet. The same observer informs us, that, by examining the variation in the daily appearance of the horns or cusps of this planet, when it appeared of a crescent form, he found the period of its diurnal rotation round its axis to be twenty-four hours, five minutes, and twenty-eight seconds. But these deductions require still to be confirmed by future observations.

The light or the intensity of solar radiation which falls on this planet is nearly seven times greater than that which falls upon the earth; for the proportion of their distances from the sun is nearly as three to eight, and the quantity of light diffused from a luminous body is as the square of the distance from that body. The square of 3 is 9, and the square of 8, 64, which, divided by 9, produces a quotient of 7 1-9, which nearly expresses the intensity of light on Mercury compared with that on the earth. Or, more accurately, thus: Mercury is 36,880,000 of miles from the sun, the square of which is 1,360,134,400,000,000: the earth is distant 95,000,000, the square of which is, 9,025,000,000,000,000. Divide this last square by the first, and the quotient is about 6⅔, which is very nearly the proportion of light on this planet. As the apparent diameter of the sun is likewise in proportion to the square of the distance, the inhabitants of this planet will behold in their sky a luminous orb, giving light by day, nearly seven times larger than the sun appears to us; and every object on its surface will be illuminated with a brilliancy seven times greater than are the objects around us in a fine summer's day. Such a brilliancy of luster on every object would completely dazzle our eyes in their present state of organization; but in every such case we are bound to believe that the organs of vision of the inhabitants of any world are exactly adapted to the sphere they occupy in the system to which they belong. Were we transported to such a luminous world as Mercury, we could perceive every object with the same ease and distinctness we now do, provided the pupil of the eye, instead of being one-eighth of an inch in diameter, as it now is, were contracted to the size of one-fiftieth of an inch. In consequence of the splendor which is reflected from every object on this planet, it is likely that the whole scenery of nature will assume a most glorious and magnificent aspect, and that the *colors* depicted on the various parts of the scenery of that world will be much more *vivid* and *splendid* than they appear on the scenery of our terrestrial mansion; and since it appears highly probable that there are elevated mountains on this planet, if they be adorned with a diversity of color, and of rural and artificial objects, they must present to the beholder a most beautiful, magnificent, and sublime appearance. The following figures will present to the eye a comparative view of the apparent size of the sun, as beheld from Mercury and from the earth.

Fig. 8.



Diameter of the Sun as seen from Mercury.
Diameter of the Sun as seen from the Earth.

While the intensity of the solar light on this planet is about seven times greater than on the earth, the light on the surface of Uranus, the most distant planet of the system, is 360 times less than that on the earth; for the square of the earth's distance, as formerly stated, is 9,025,000,000,000,000, and the square of the distance of Uranus from the sun, 1,800,000,000, of miles, is 3,240,000,000,000,000,000, which, divided by the former number, gives a quotient of 359 and a fraction, or, in round numbers, 360; the number of times that the light on the earth exceeds that on Uranus. Yet we find that the light reflected from that distant planet, after passing 1,800,000,000 of miles from the body of the sun, and returning again by reflection 1,700,000,000 of miles to the earth, is visible through our telescopes, and even sometimes to the naked eye. Thus it appears that the intensity of light at the two extremes of the solar system is in the proportion of 2400 to 1; for 3606×⅔=2400, the number of times that the quantity of light on Mercury exceeds that on Uranus. But we may rest assured, from what we know of the plans of Divine wisdom, that the eyes of organic intelligence, both at the extremes and in all the intermediate spaces of the system, are exactly adapted to the sphere they occupy and the quantity of light they receive from the central luminary.

In regard to the *temperature* of Mercury, if the intensity of *heat* were supposed to be governed by the same law as the intensity of light, the heat in this planet would, of course, be nearly seven times greater than on the earth. Supposing the average temperature of our globe to be fifty degrees of Fahrenheit's thermometer, the average temperature on Mercury would be 333 degrees, or 121 degrees above the heat of boiling water; a degree of heat sufficient to melt sulphur, to make nitrous acid boil, and to dissipate into vapor every volatile compound. But we have no reason to conclude that the degree of sensible heat on any planet is in an inverse proportion to its distance from the sun. We have instances of the contrary on our own globe. On the top of the highest range of the Andes, in South America, there is an intense cold at all times, and their summits are covered with perpetual snows, while in the plains immediately adjacent, the inhabitants feel all the effects of the scorching rays of a tropical sun. The sun, during our summer in the northern hemisphere, is more than three millions of miles further from us than in winter; and although the obliquity of his rays is partly the cause of the cold felt in winter when he is nearest us, yet it is not the *only* cause; for we find that the cold in New York and Pennsylvania is more intense in winter than in Scotland, although the sun rises from ten to sixteen degrees higher above the horizon in the former case than in the latter. Beside, we find that the heat of summer in the southern hemisphere, *when the sun is nearest to the earth*, is not so great as in the summer of corresponding latitudes in the northern hemisphere. In short, did heat depend chiefly on the nearness of the sun or the obliquity of his rays, we should always have the same degree of heat or cold at the same time of the year, in a uniform circle; which experience proves to be contrary to fact. The degree of heat, therefore, on any planet, and on different portions of the same planet, must depend in part, and perhaps chiefly, on the nature of the atmosphere, and other circumstances connected with the constitution of the planet, in combination with the influence of the solar rays. These rays undoubtedly produce heat, but the degree of its intensity will depend on the nature of the substances on which they fall; as we find that the same degree of sensible heat is not felt when they fall on a piece of iron or marble, as when they fall on a piece of wood or flannel.

Mercury was long considered as the smallest primary planet in the system; but the four new planets lately discovered between the orbits of Mars and Jupiter, are found to be smaller. Its diameter is estimated at 3200 miles, and, consequently, its surface contains above 32,000,000 of square miles, and its solid contents are 17,157,324,800, or more than seventeen thousand millions of solid miles; and if the number of solid miles contained in the earth, which are 264,000,000,000, be divided by this sum, the quotient will be somewhat more than fifteen, showing that the earth is above fifteen times larger than Mercury. Notwithstanding the comparatively diminutive size of this planet, it is capable of containing a population upon its surface much greater than has ever been supported on the surface of the earth during any period of its history. In making an estimate on this point, I shall take the population of England as a standard. England contains 50,000 square miles of surface, and 14,000,000 of inhabitants, which is 280 inhabitants for every square mile. The surface of Mercury contains 32,000,000 of square miles, which is not much less than all the habitable parts of our globe. At the rate of population now stated, it is sufficiently ample to contain 8,960,000,000, or eight thousand nine hundred and sixty millions of inhabitants, which is more than eleven times the preset population of our globe. And although the one-half of the surface of this planet were to be considered as covered with water, it would still contain nearly six times the population of the earth. Hence it appears, that small as this planet may be considered, when compared with others, and seldom as it is noticed by the vulgar eye, it in all probability holds a far more distinguished rank in the intellectual and social system under the moral government of God, than this terrestrial world of which we are so proud, and all the living beings which traverse its surface.

I shall only mention further the following particulars in reference to this planet. In its revolution round the sun, its motion is swifter than that of any other planet yet discovered; it is no less than at the rate of 109,800 miles every hour at an average, although in some parts of its course it is slower, and in other parts swifter, since it moves in an elliptical orbit. Of course it flies 1830 miles every minute, and more than thirty miles during every beat of our pulse. The *density* of this planet is found by certain physical calculations and investigations, founded on the laws of universal gravitation, to be nine times that of water, or equal to that of lead; so that a ball of lead 3200 miles in diameter would exactly poise the planet Mercury. This density is greater than that of any of the other planets, and nearly twice the density of the earth. The *mass* of this planet, or the *quantity of matter* it contains, when compared with the mass of the sun, is, according to La Place, as 1 to 2,025,810, or about the two millionth part; that is, it would require two millions of globes of the size and density of Mercury to weigh one of the size and density of the sun. But as Mercury contains a much greater quantity of matter in the same bulk than the sun, *in point of size* it would require 22,000,000 of globes of the bulk of Mercury to compose a body equal to that of the sun. In consequence of the great density of this planet, bodies will have a greater weight on its surface than on the earth. It has been computed, that a body weighing one pound on the earth's surface would weigh one pound eight and a half drachms on the surface of Mercury. If the centrifugal force of this planet were suspended, and its motion in a circular course stopped, it would fall toward the sun, as a stone when thrown upward falls to the ground, by the force of gravity, with a velocity continually increasing as the square of the distance from the sun diminished. The time in which Mercury or any other planet would fall to the sun by the centripetal force, or the sun's attraction, is equal to its periodic time divided by the square root of thirty-two; a principle deduced from physical and mathematical investigation. Mercury would therefore fall to the sun in 15 days, 13 hours; Venus in 39 days, 17 hours; the earth in 64 days, 13 hours; Mars in 121 days, 10 hours; Vesta in 205 days; Ceres in 297 days, 6 hours; Pallas in 301 days, 4 hours; Juno in 354 days, 19 hours; Jupiter in 765 days, 19 hours, or above two years; Saturn in 1901 days, or about five years; Uranus in 5425 days, or nearly fifteen years; and the Moon would fall to the earth, were its centrifugal force destroyed, in 4 days, 20 hours. Some of the deductions stated above may be apt to startle some readers as beyond the powers of limited intellects, and above the range of human investigation. The discoveries of Newton, however, have now taught us the laws by which these bodies act upon one another; and as the effects they produce depend very much upon the quantities of matter they contain, by observing these effects we are able, by the aid of mathematical reasoning, to determine the quantities of matter in most of the planets with considerable certainty. But to enter on the demonstration of such points would require a considerable share of attention and of mathematical knowledge, and would probably prove tedious and uninteresting to the general reader.

Mercury revolves in an orbit which is elliptical, and more eccentric than the orbits of most of the other planets, except Juno, Ceres, and Pallas. Its *eccentricity*, or the distance of the sun from the center of its orbit, is above 7,000,000 of miles.—The time between its greatest elongations from the sun varies from 106 to 130 days. Its orbit is inclined to the ecliptic, or the plane of the earth's orbit, in an angle of seven degrees, which is more than double the inclination of the orbit of Venus.

II. OF THE PLANET VENUS.

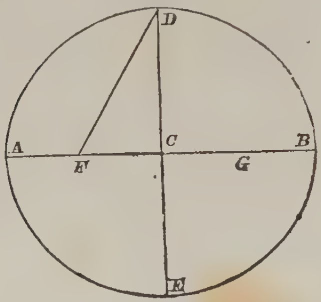
Of all the luminaries of heaven, the sun and moon excepted, the planet Venus is the most conspicuous and splendid. She appears like a brilliant lamp amid the lesser orbs of night, and alternately anticipates the morning dawn and ushers in the evening twilight. When she is to the westward of the sun, in winter, she cheers our mornings with her vivid light, and is a prelude to the near approach of the break of day and the rising sun. When she is eastward of that luminary, her light bursts upon us after sunset, before any of the other twinkling orbs of heaven make their appearance; and she discharges, in some measure, the functions of the absent moon. The brilliancy of this planet has been noticed in all ages, and has been frequently the subject of description and admiration both by shepherds and by poets. The Greek poets distinguished it by the name of *Phosphor* when it rose before the sun, and *Hesperus* when it appeared in the evening after the sun retired; and it is now generally distinguished by the name of the Morning and Evening Star.

> "Next Mercury, Venus runs her larger round,
> With softer beams and milder glory crown'd,
> Friend to mankind, she glitters from afar,
> Now the bright *evening*, now the *morning* star.
> From realms remote she darts her pleasing ray,
> Now leading on, now closing up the day;
> Term'd *Phosphor* when her *morning* beams she yields,
> And *Hesp'rus* when her ray the *evening* gilds."

Before proceeding to a more particular description of this planet, I shall lay before the reader a brief explanation of the nature of the planetary orbits, as I may have occasion to refer to certain particulars connected with them in the following descriptions. All the planets and their satellites move in elliptical orbits, more or less eccentric. The following figure exhibits the form of these orbits.

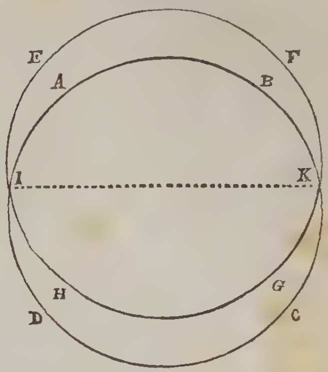
The figure *A D B E* represents the form of a planetary orbit, which is that of an oval or ellipse. The longest diameter is *A B*; the shorter diameter *D E*. The two points *F* and *G* are called the *foci* of the ellipse, around which, as two central points, the ellipse is formed. The sun is not placed in *C*, the center of the orbit, but at *F*, one of the foci of the ellipse. When the planet, therefore, is at *A*, it is nearest the sun, and is said to be in its *perihelion;* its distance from the sun gradually increases until it reaches the opposite point, *B*, when it is at its greatest distance from the sun, and is said to be in its *aphelion;* when it arrives at the points *D* and *E* of its orbit, it is said to be at the *mean distance.* The line *A B*, which joins the perihelion and aphelion, is called the *line of the apsides*, and also the greater axis or the *transverse* axis of the orbit; *D E* is the *lesser* or *conjugate* axis; *F D*, the *mean distance* of the planet from the sun; *F C*, or *G C*, the *eccentricity* of the orbit, or the distance of the sun from its center; *F* is the *lower focus*, or that in which the sun is placed; *G* the *higher focus; A* the *lower apsis*, and *B* the *higher apsis.* The orbits of some of the planets are more elliptical than others.—The eccentricity of the orbit of Mercury is above 7,000,000 miles; that is, the distance from the point *F*, where the sun is placed, to the center, *C*, measures that number of miles; while the eccentricity of Venus is only about 490,000 miles, or less than half a million. Most of the planetary orbits, except those of some of the new planets, approach very nearly to the circular form.

Fig. 9.



The orbits of the different planets do not all lie in the same plane, as they appear to do in orreries and in the representations generally given of the solar system. If we suppose a plane to pass through the earth's orbit, and to be extended in every direction, it will trace a line in the starry heavens which is called the *ecliptic*, and the plane itself is called the *plane of the ecliptic.* The orbits of all the other planets do not lie in this plane, one half of each orbit rising above it, while the other half falls below it. This may be illustrated by supposing a large bowl or concave vessel to be nearly filled with water; the surface of the water will trace a circular line round the inner surface of the bowl, which may represent the ecliptic, while the surface of the water itself is the *plane* of the ecliptic, and the bowl is the one-half of the concave sky. If we now immerse in the bowl a large circular ring obliquely, so that one-half of it is above the surface of the water and the other half below, this ring will represent the orbit of a planet inclined to the ecliptic or to the fluid surface; or if we take two large rings or hoops of nearly equal size, and place the one within the other obliquely, so that the half of the one hoop may be above, and the opposite half below the other hoop, it will convey an idea of the inclination of a planet's orbit to the plane of the ecliptic. Thus, if the circle *E F G H* (Fig. 10) represent the plane of the earth's orbit or the ecliptic, the circle *A B C D* may represent the orbit of a planet which is inclined to it; the semicircle *I A B K* being below the level of the ecliptic, and the other half or semicircle being above it. The points of intersection at *I* and *K*, where the circles cut one another, are called the *nodes.* If the planet is moving in the direction *A I D*, the point *I*, where it ascends above the plane, is called the *ascending node,* and the opposite point, *K*, the *descending node.* The line *I K*, which joins the nodes, is called the *line of the nodes*, which, in the different planetary orbits, points to different parts of the heavens. It is when Mercury and Venus are at or near the line of the nodes that they appear to make a transit across the sun's disc. The moon's orbit is inclined to the plane of the earth's orbit in an angle of about five degrees; and it is only when the full moon or change happens at or near the *nodes* that an eclipse can take place, because the sun, moon, and earth are then nearly in the same plane; at all other times of full or change, the shadow of the moon falls either above or below the earth, and the shadow of the earth either above or below the moon. The ecliptic is supposed to be divided into twelve signs, or 360 degrees, which have received the names:—*Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces.*—Each of these signs is divided into thirty equal parts, called *degrees;* each degree into sixty parts, or minutes; each minute into sixty parts, or seconds, &c.

Fig. 10.

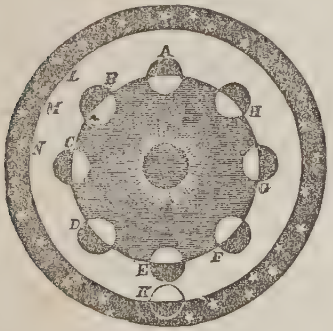


Having stated the above definitions, which it may be useful to keep in mind in our further discussions, I shall proceed to a particular description of the motions and other phenomena of Venus.

General Appearances and apparent motions of Venus.—This planet, as already noticed, is only seen for a short time, either after sunset in the evening, or in the morning before sunrise. It has been frequently seen by means of the telescope, and sometimes by the naked eye, at noonday, but it was never seen at midnight, as all the other planets may be, with the exception of Mercury. It never appears to recede further from the sun than forty-seven degrees, or about half the distance from the horizon to the zenith. Of course, it was never seen rising in the east, or even shining in the south, after the sun had set in the west, as happens in regard to all the other heavenly bodies, with the exception now stated.

When this planet, after emerging from the solar rays, is first seen in the evening, it appears very near the horizon about twenty minutes after sunset, and continues visible only for a very short time, and descends below the horizon not far from the point where the sun went down. Every succeeding day its apparent distance from the sun increases; it rises to a higher elevation, and continues a longer time above the horizon. Thus it appears to move gradually eastward from the sun for four or five months, until it arrives at the point of its greatest elongation, which seldom exceeds forty-seven degrees, when it appears for some time stationary; after which it appears to commence a retrograde motion from east to west, but with a much greater degree of apparent velocity; approaching every day nearer the sun, and continuing a shorter time above the horizon, until, in the course of two or three weeks, it appears lost in the splendor of the solar rays, and is no longer seen in the evening sky until more than nine or ten months have elapsed. About eight or ten days after it has disappeared in the evening, if we look at the eastern sky in the morning, a little before sunrise, we shall see a bright star very near the horizon, which was not previously to be seen in that quarter; this is the planet Venus, which has passed its inferior conjunction with the sun, and has now moved to the westward of him, to make its appearance as the morning star. It now appears every succeeding day to move pretty rapidly from the sun to the westward, until it arrives at the point of its greatest elongation, between 45° and 48° distant from the sun, when it again appears stationary; and then returns eastward, with an apparently slow motion, until it is again immersed in the sun's rays, and arrives at its superior conjunction, which happens after the lapse of about nine months from the time of being first seen in the morning. But the planet is not visible to the naked eye all this time on account of its proximity to the sun when slowly approaching its superior conjunction. After passing this conjunction it soon after appears in the evening, and resumes the same course as above stated. During each of the courses now described, when viewed with a telescope, it is seen to pass successively through all the phases of the moon, appearing *gibbous*, or nearly round, when it is first seen in the evening; of the form of a half moon when about the point of its greatest elongation; and of the figure of a crescent, gradually turning more and more slender as it approaches its inferior conjunction with the sun. Such are the general appearances which Venus presents to the attentive eye of a common observer, the reasons of which will appear from the following figure and explanations.

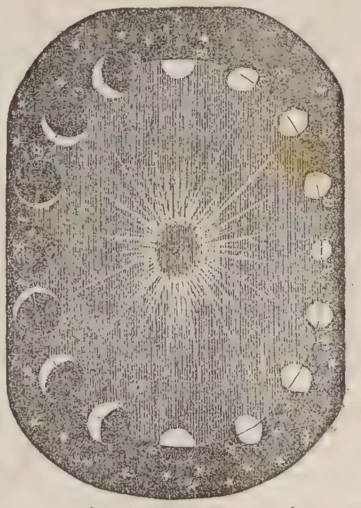
Fig. 11.



Let the earth be supposed at *K*; then when Venus is in the position marked *A*, it is nearly in a line with the sun as seen from the earth, in which position it is said to be in its *superior* conjunction with the sun, or beyond him, in the remotest part of its orbit from the earth; in which case the body of the sun sometimes interposes between the earth and Venus; at other times it is either a little above or below the sun, according as it happens to be either in north or south latitude. When it is in this position, the whole of its enlightened hemisphere is turned toward the earth. As it moves on its orbit from *A* to *B*, which is from west to east, and is called its *direct* motion, it begins to appear in the evening after sunset. When it arrives at *B*, it is seen among the stars at *L*, in which position it assumes a gibbous phase, as a portion of its enlightened hemisphere is turned from the earth. When it arrives at *C*, it appears among the stars at *M*, at a still greater distance from the sun, and exhibits a less gibbous phase, approaching to that of a half moon. When arrived at *D*, it is at the point of its greatest eastern elongation, when it appears like a half moon, and is seen among the stars at *N*; it now appears for some time stationary; after which it appears to move with a rapid course in an opposite direction, or from east to west, during which it presents the form of a crescent, until it approaches so near the sun as to be overpowered with the splendor of his rays. When arrived at *E*, it is said to be in its *inferior* conjunction, and, consequently, nearest the earth. In this position it is just 27 millions of miles from the earth; whereas, at its superior conjunction, it is no less than 163 millions of miles from the earth, for it is then farther from us by the whole diameter of its orbit, which is 136 millions of miles. This is the reason why it appears much smaller at its superior conjunction than when near its inferior; although, in the latter case, there is only a small crescent of its light presented to us, while in the former case its full enlightened hemisphere is turned to the earth.

The following figure will exhibit more distinctly the *phases* of this planet in the different parts of its course, and the reason of the difference of its apparent magnitude in different points of its orbit. At *A* it is in the superior conjunction, when it presents to our view a round full face. At *B* it appears as an evening star, and exhibits a gibbous phase, somewhat less than

Fig. 12



full moon. At *D* it approaches somewhat nearer to a half moon. At *E*, near the point of its eastern elongation, it appears like a half moon. During all this course it moves from west to east. From *F* to *I* it appears to move in a contrary direction, from east to west, during which it assumes the figure of a crescent, gradually diminishing in breadth, but increasing in extent, until it arrives at *I*, the point of its inferior conjunction, when its dark hemisphere is turned toward the earth, and is consequently invisible, being in a situation similar to that of the moon at the time of change. It is seen no longer in the evenings, but soon appears in the morning under the figure of a slender crescent, and passes through all the other phases represented in the diagram, at *M, N, O*, &c., until it arrives again at *A*, its superior conjunction. The earth is here supposed to be placed at *K;* and if it were at rest in that position, all the changes now stated would happen in the course of 224 days. But as the earth is moving forward in the same direction as the planet, it requires some considerable time before Venus can overtake the earth, so as to be in the same position as before with respect to the earth and the sun. The time, therefore, that intervenes between the superior conjunction and the same conjunction again, is nearly 584 days, during which period Venus passes through all the variety of its motions and phases as a morning and evening star.

This diversity of motions and phases, as formerly stated, serves to prove the truth of the system, now universally received, which places the sun in the center, and the earth beyond the orbit of Venus. In order to illustrate this point to the astronomical tyro in the most convincing manner, I have frequently used the following plan With the aid of a planetarium, and by means of an ephemeris or a nautical almanac, I place the earth and Venus in their true positions on the planetarium, and then desire the learner to place his eye in a line with the balls representing Venus and the earth, and to mark the *phase* of Venus, as seen from the earth, whether gibbous, a half moon, or a crescent. I then adjust an equatorial telescope (if the observation be in the day-time), and, pointing it to Venus, show him this planet *with the same phase* in the heavens; an experiment which never fails to please and to produce conviction.

It has generally been asserted by astronomers that it is impossible to see Venus at the time of its superior conjunction with the sun. Mr. Benjamin Martin, in his "Gentleman and Lady's Philosophy," vol. i, says, "At and about her upper conjunction Venus cannot be seen, by reason of her nearness to the sun." And in his "Philosophia Britannica," vol. iii, the same opinion is expressed: "At her superior conjunction Venus would appear a full enlightened hemisphere, *were it not that she is then lost in the sun's blaze,* or hidden behind his body." Dr. Long, in his "Astronomy," vol. i, says, "Venus, in her superior conjunction, *if she could be seen,* would appear round like the full moon." Dr. Brewster, in the article of *Astronomy* in the "Edinburgh Encyclopædia," when describing the phases of Mercury and Venus, says, "Their luminous side is completely turned to the earth at the time of their superior conjunction, when they would appear like the full moon, *if they were not then eclipsed by the rays of the sun.*" The same opinion is expressed in similar phrases by Ferguson, Gregory, Adams, Gravesend, and most other writers on the science of astronomy, and has been copied by all subsequent compilers of treatises on this subject. In order to determine this point, along with several others, I commenced, in 1813, a series of observations on the celestial bodies *in the day-time*, by means of an equatorial instrument. On the 5th of June that year, a little before midday, when the sun was shining bright, I saw Venus distinctly with a magnifying power of sixty times, and a few minutes afterward with a power of thirty, and even with a power of fifteen times. At this time the planet was just 3° in longitude and about $13'$ in time east of the sun's center, and, of course, only $2\frac{3}{4}^\circ$ from the sun's limb. Cloudy weather prevented observations when Venus was nearer the sun.[*] On the 16th of October, 1819, an observation was made, in which Venus was seen when only six days and nineteen hours past the time of her superior conjunction. Her distance from the sun's eastern limb was then only $1^\circ\ 28'\ 42''$. A subsequent observation proved that she could be seen when only $1^\circ\ 27'$ from the sun's margin, which approximates to the nearest distance from the sun at which Venus is distinctly visible. About the 10th of March, 1826, I had a glimpse of this planet within a few hours of its superior conjunction, but the interposition of clouds prevented any particular or continued observations. It was then about $1^\circ\ 25\frac{1}{2}'$ from the sun's center. Observations were likewise made to determine how near its *inferior* conjunction this planet might be seen. The following is the observation in which it was seen nearest to the sun. On March 11th, 1822, at thirty minutes past twelve, noon, the planet being only thirty-five hours past the point of its inferior conjunction, I perceived the crescent of Venus by means of an equatorial telescope, magnifying about seventy times. It appeared extremely slender, but distinct and well-defined, and apparently of a larger curve than that of the lunar crescent when the moon is about two days old. The difference of longitude between the sun and Venus at that time was about $2^\circ\ 19'$. A gentleman who happened to be present perceived the same phenomenon with the utmost ease and perfect distinctness.[†]

From the above observations, the following conclusions are deduced: 1. That Venus may be distinctly seen at the moment of her superior conjunction, with a moderate magnifying power, when her geocentric latitude[‡] at the time of conjunction exceeds $1\frac{1}{2}^\circ$, or, at most, $1^\circ\ 43'$. 2. That during the space of 584 days, or about nineteen months, the time Venus takes in moving from one conjunction of the sun to a like conjunction again, when her latitude at the time of her superior conjunction exceeds 1° 43′, she *may be seen by means of an equatorial telescope every clear day without interruption*, except at the moment of her inferior conjunction, and a very short time before and after it, a circumstance which cannot be affirmed of any other celestial body, the sun only excepted. 3. That from the time when Venus ceases to be visible, prior to her inferior conjunction, on account of the smallness of her crescent and her proximity to the sun, to the moment when she may again be perceived in the day-time by an equatorial telescope, there elapses a period of only two days and twenty-two hours; or, in other words, Venus can never be hidden from our view about the time of her inferior conjunction for a longer period than seventy hours. 4. That during the space of 584 days, the longest period in which Venus can be hidden from our view under any circumstances, excepting a cloudy atmosphere, is about sixteen days and a half.—During the same period, this planet sometimes will be hidden from the view of a common observer for the space of five or six months.

---

[*] The particulars connected with this observation, and with those made on the other planets, and on stars of the first and second magnitudes, together with a description of the instrument, and the manner of making day observations are recorded in Nicholson's "Journal of Natural Philosophy," &c., for October, 1813, vol. xxxvi, pp. 109 to 128, in a communication which occupies about twenty pages; and also, in an abridged form, in the "Monthly Magazine," "Annals of Philosophy," and other periodical journals of that period. During the succeeding winter the celebrated Mr. Playfair, professor of natural philosophy in the University of Edinburgh, communicated, in his lectures to the students, the principal details contained in that communication as *new facts* in astronomical science.

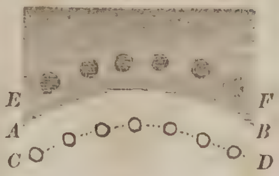
[†] The observations stated above are also recorded in scientific journals. The observation of the 16th October, 1819, is recorded in the "Edinburgh Philosophical Journal," No. V, for July, 1820, pp. 191, 192; and in Dr. Brewster's *second* edition of "Ferguson's Astronomy," vol. ii, p. 111 in the "Monthly Magazine" for August, 1820, vol. i, p. 62 The observation of March 11, 1822, made on Venus when near the *inferior* conjunction, is recorded at large in the "Edinburgh Philosophical Journal," No. XIII, July, 1822, pp. 177, 178, &c.

[‡] The *latitude* of a heavenly body is its distance from the ecliptic, or the apparent path of the sun, either north or south. Its *geocentric* latitude is its latitude as seen from the earth. Its *heliocentric* latitude is its latitude as viewed from the sun. These latitudes seldom coincide.

One practical use of the above observations is, that they may lead to the determination of the difference (if any) between the polar and equatorial diameters of this planet, which point has never yet been determined. It is well known that the earth is of a spheroidal figure, having its polar shorter than its equatorial diameter. Jupiter, Mars, and Saturn have also been ascertained to be oblate spheroids, and the proportion between their equatorial and polar diameters has been pretty accurately determined. As Venus is found to have a rotation round her axis, as these planets have, it is reasonable to conclude that she is of a similar figure. It is impossible, however, to determine this point when she is in those positions in which she has generally been viewed; as at such times she assumes either a gibbous phase, the form of a half moon, or that of a crescent, in neither of which cases can the two diameters be measured. I am therefore of opinion that, at some future conjunction, when her geocentric latitude is considerable, with a telescope of a high magnifying power, furnished with a micrometer, this point might be ascertained. If the planet is then viewed at a high latitude, and the sky serene, its disc will appear sufficiently luminous and well-defined for this purpose; free of that glare and tremulous aspect it generally exhibits when near the horizon, which makes it appear larger than it ought to do, and prevents its margin from being accurately distinguished.

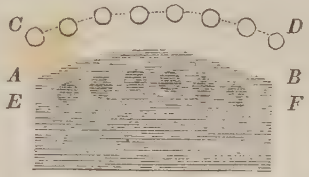
Such observations require a considerable degree of attention and care, and various contrivances for occasionally diminishing the aperture of the object-glass, and for preventing the direct rays of the sun from entering the tube of the telescope. In order to view this planet to advantage at any future conjunction, when in *south* latitude, it will be proper to fix a board, or any other thin opaque substance, at a considerable distance beyond the object end of the telescope, having such a degree of concave curvature as shall nearly correspond with a segment of the diurnal arc at that time described by the sun, with its lower concave edge at an elevation a small degree above the line of collimation of the telescope, when adjusted for viewing the planet, in order to intercept as much as possible the solar rays. When the planet is in *north* latitude, the curvature of the board must be made *convex*, and placed a little below the line of sight.

Fig. 13



The above figure will illustrate my idea; where *A B* (Fig. 13) represents the concave curve of the board to be used when the planet is in south latitude; *C D*, a segment of the apparent diurnal path of the planet; and *E F*, a segment of the sun's diurnal arc. Fig. 14, represents the board to be used when the planet is in *north* latitude, which requires no further description. I have given the above brief statement of the observations on Venus because they are not yet generally known, and because compilers of elementary books on astronomy still reiterate the vague and unfounded assertion that it is impossible to see this planet at its superior conjunction, when it presents a full enlightened hemisphere. The circumstance now ascertained may not be considered as a fact of much importance in astronomy. It is always useful, however, in every department of science, to ascertain every fact connected with its principles, however circumstantial and minute, as it tends to give precision to its language; as it enables the mind to take into view every particular which has the least bearing on any object of investigation; and as it may ultimately promote its progress by leading to conclusions which were not at first apprehended. One of these conclusions or practical uses has been stated above; and another conclusion is, that such observations as now referred to may possibly lead to the discovery of planets yet unknown within the orbit of Mercury, which circumstance I shall take occasion more particularly to explain in the sequel.

Fig. 14.



Discoveries made by the Telescope in relation to Venus.—The first circumstance which attracted the attention of astronomers after the invention of the telescope, was, the variety of phases which Venus appeared to assume, of which I have already given a description. Nothing further was observed to distinguish this planet until more than half a century had elapsed, when Cassini, a celebrated French astronomer, in the years 1666–7, discovered some spots on its surface, by which he endeavored to ascertain the period of its revolution round its axis. October 14th, 1666, at five hours forty-five minutes, P. M., he saw a bright spot near the limits between the light and the dark side of the planet, not far from its center; at the same time he noticed two dark oblong spots near the west side of the disc, as represented in Fig. 15. After this he could obtain no satisfactory views of Venus until April 20th, 1667, about fifteen minutes before sunrise, when he saw upon the disc, now half enlightened, a bright part, distant from the southern edge about a fourth part of the diameter of the disc, and near the eastern edge. He saw, likewise, a darkish oblong spot toward the northern edge, as in Fig. 16. At sunrise he perceived that the bright part was advanced farther from the southern point than when he first observed it, as at Fig. 17, when he had the satisfaction of finding an evident proof of the planet's motion. On the next day, at sunrise, the bright spot was a good way off the section, and distant from the southern point a fourth part of the diameter of the disc. When the sun had risen six degrees above the horizon, the spot had got beyond the center. When the sun had risen seven degrees, the section cut it in halves, as in Fig. 18, which showed its motion to have some inclination toward the center.* Several observations of a similar kind were made about that time, which led Cassini to the conclusion that the planet revolves about its axis in a period somewhat more than twenty-three hours. From this time, for nearly sixty years, we have no further accounts of spots having been observed on the disc of Venus.

Fig. 15. Fig. 16.

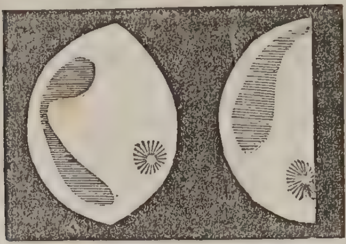


Fig 17. Fig. 18.

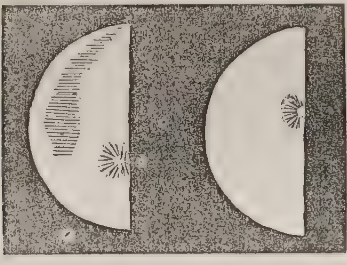
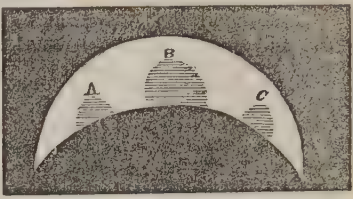


In the year 1726, *Bianchini*, with telescopes of 90 and 100 Roman palms, commenced a series of observations on Venus, and published an account of them in a book entitled, "*Hesperi et Phosphori nova Phenomena.*" In these observations, we do not find that any one of them was continued long enough to discover any change of position in the spots at the end of the observation from what there was at the beginning; but at the distance of two and of four days he found the same spot advanced so far that he concluded it must have gone round at the rate of 15° in a day. This advance would show that Venus turned round either once in about twenty-four days, or in little more than twenty-three hours, but would not determine which of these was the true period. For, if an observer, at a given hour, suppose seven in the evening, were to mark the exact place of a spot, and at the same hour on the next day find the spot advanced 15°, he would not be able to determine whether the spot, during that interval of twenty-four hours, had advanced forward only 15°, or had finished a revolution, and 15° more as a part of another rotation.* Of these two periods, Bianchini concluded that the rotation was accomplished in twenty-four days eight hours. The following is the chief, if not the only observation, he brings forward to substantiate his conclusion He saw three spots, *A*, *B*, *C*, in the situation represented in Fig. 19, which he and several persons of distinction viewed for about an hour when they could discover no change of place in their appearance. Venus being hidden behind the Barbarini palace, their view was interrupted for nearly three hours, at the end of which they found that the spots had not sensibly changed their situation. But the inference from this observation is not conclusive for the period of twenty-four days eight hours. For, during the three hours' interruption, the spot *C* might have gone off the disc, and the spot *B* moved into its place, where, being near the edge, it would appear less than when in the middle; *A*, succeeding into the place of *B*, would appear larger than it did near the edge, and another spot might have come into the place of *A*. For that there were other spots, particularly one which, by the rotation of Venus, would have been brought into the place of *A*, appears by the figures given by Bianchini; and if so, it would correspond with the rotation of twenty-three hours twenty minutes deduced by Cassini. Beside, it is impossible to make observations on Venus for three or four hours in succession, as is here supposed, without the help of equatorial instruments, which were not then in use, as this planet is seldom more than three hours above the horizon after sunset; and when it descends within 8° or 10° of the horizon, it is impossible to see its surface with any degree of distinctness, on account of the brilliancy of its light, and the undulating vapors near the horizon, which, in some cases, prevent even its phase from being accurately distinguished. In the communication in "Nicholson's Journal" for 1813, already referred to, I have shown how the dispute in reference to the rotation of Venus may be settled, by commencing a series of observations on this planet in the day-time, when its spots, if any were perceived, could be traced in their motion for twelve hours or more. Mr. Ferguson, in his astronomy, by adopting the conclusion of Bianchini, has occupied a number of pages in describing the phenomena of Venus on this supposition, which description is altogether useless, and conveys erroneous ideas of the circumstances connected with this planet, if the period determined by Cassini (as is most probable) be correct.

Fig. 19.



Mr. Schroeter, formerly mentioned, who has been a most diligent and accurate observer of the heavens, commenced a series of observations, in order to determine the daily period of this planet

---

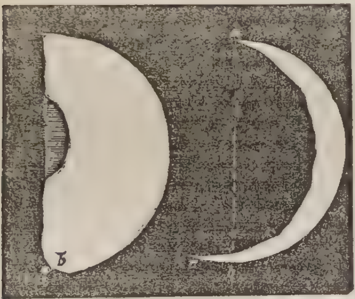
* See "Philosophical Transactions," abridged by Drs. Hutton, Shaw, and Pearson, vol. i, part 2, p. 217; "Journal des Savans," vol. i, p. 216; and "*Memoires* of the Royal Academy of Sciences."

* See some particular remarks on this subject, illustrated with a figure, in my volume "On the Improvement of Society," section 3.

He observed particularly the different shapes of the two horns of Venus. Their appearance generally varied in a few hours, and became nearly the same at the corresponding time of the subsequent day, or, rather, about half an hour sooner every day. Hence he concluded that the period must be about twenty-three hours and a half; that the equator of the planet is considerably inclined to the ecliptic, and its pole at a considerable distance from the point of the horn. From several observations of this kind he found that the period of rotation must be twenty-three hours, twenty-one minutes, or only one minute more than had been assigned by Cassini; and this, we have reason to believe, is about the true period of this planet's revolution round its axis, being thirty-five minutes less than the period of the earth's rotation, which is twenty-three hours fifty-six minutes. I have stated these observations respecting the rotation of Venus at some length, because they are not generally known to common readers on this subject, or noticed in modern elementary books on astronomy, and that the general reader may perceive the reason of the dispute which has arisen among astronomers on this point.

Mountains on Venus.—Mr. Schroeter, in his observations, discovered several mountains on this planet, and found that, like those of the moon, they were always highest in the southern hemisphere; their perpendicular hights being nearly as the diameters of their respective planets. From the 11th of December, 1789, to the 11th of January, 1790, the southern horn, *b* (Fig. 20), appeared much blunted, with an enlightened mountain, *m*, in the dark hemisphere, which he estimated at about 18,300 toises, or nearly twenty-two miles in perpendicular hight. It is quite obvious that if such a bright spot as here represented was regularly or periodically seen, it must indicate a very high elevation on the surface of the planet, and its precise hight will depend upon its distance from the illuminated portion of the disc, or, in other words, the length of its shadow. It is precisely in such a way that the mountains in the moon are distinguished. Mr. Schroeter measured the altitude of other three mountains, and obtained the following results: hight of the first, nineteen miles, or about five times the hight of Chimborazo; hight of the second, eleven miles and a half; and of the third, ten miles and three quarters. These estimates may, perhaps, require certain corrections in future observations.

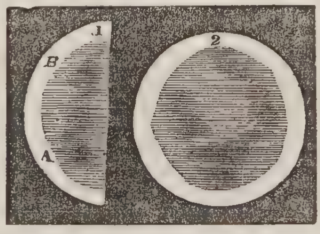
Fig. 20. Fig. 21



Atmosphere of Venus.--From several of Mr. Schroeter's observations, he concludes that Venus has an atmosphere of considerable extent. On the 10th of September, 1791, he observed that the southern cusp of Venus disappeared, and was bent like a hook about eight seconds beyond the luminous semicircle into the dark hemisphere. The northern cusp had the same tapering termination, but did not encroach upon the dark part of the disc. A streak, however, of glimmering bluish light proceeded about eight seconds along the dark line, from the point of the cusp, from *b* to *c* (Fig. 21), *b* being the extremity of the diameter of *a b*, and consequently, the natural termination of the cusp. The streak *b c*, verging to a pale gray, was faint when compared with the light of the cusp at *b*. I was struck with a similar appearance when observing Venus, when only thirty-five hours past her inferior conjunction, on March 11, 1822, as formerly noticed (p. 32). One of the cusps, at least, appeared to project into the dark hemisphere, like a fine lucid thread, beyond the luminous semicircle. This phenomenon Mr. Schroeter considers as the *twilight*, or crepuscular light of Venus. From these and various other observations, which it would be too tedious to detail, he concludes, on the ground of various calculations, that the *dense* part of the atmosphere of Venus is about 16,020 feet, or somewhat above three miles high; that it must rise far above the highest mountains; that it is more opaque than that of the moon; and that its density is a sufficient reason why we do not discover on the surface of Venus those superficial shades and varieties of appearance which are to be seen on the other planets.

Day Observations on Venus.—The most distinct and satisfactory views I have ever obtained of this planet were taken at noonday, or between the hours of ten in the morning and two in the afternoon, when it happened to be at a high elevation above the horizon, which is generally the case during the summer months. The light of this planet is so brilliant, that its surface and margin seldom appear well-defined in the evening, even with the best telescopes. But in the daytime its disc and margin present a sharp and well-defined aspect with a good achromatic telescope, and almost completely free of those undulations which obscure its surface when near the horizon. The following figure (No. 1) represents one of the appearances of Venus which I have frequently seen in the day-time when viewing this planet at a high altitude and in a serene sky, when near the meridian, by means of a three-and-a-half feet achromatic telescope, magnifying about 150 times.

Fig. 22.



The exterior curve of the planet, as here exhibited, appeared far more lucid and bright than the interior portion. It was not a mere stripe or luminous margin, but a broad semicircle, of a breadth nearly one-third of the semidiameter of the planet. It appeared as if it were a kind of table-land, or a more elevated portion of the planet's surface, while the interior and darker part appeared more like a plain, diversified with inequalities, and two large spots, somewhat darker than the other parts, were faintly marked. The appearance was somewhat similar to that of certain portions of the level parts of the moon which lie adjacent to a ridge of mountains or a range of elevated ground. I have exhibited this view of Venus at different times to various individuals, and even those not accustomed to look through telescopes could plainly perceive it. I consider it as a corroboration of the fact, that mountains of great elevation exist on the surface of this planet. There appeared likewise some slight indentations in the boundary which separated the dark from the enlightened hemisphere, which circumstance leads to the same conclusions. If the whole hemisphere of the planet had been enlightened, it would probably have appeared as in No. 2. On the whole, I am of opinion that future discoveries in relation to Venus will be chiefly made in the day-time, by large telescopes adapted to equatorial machinery, when such instruments shall be brought into use more than they have hitherto been. Venus, however, is the only planet on which useful observations can be made in the day-time; for although several of the other planets can be perceived, even at noonday, particularly Jupiter, yet they present a very obscure and cloudy appearance compared with Venus, on account of the comparatively small quantity of solar light which falls upon their surfaces.

Supposed Satellite of Venus.—Several astronomers have been of opinion that Venus is attended with a satellite, although it is seldom to be seen. It may not be improper to give the reader an abridged view of the observations on which this opinion is founded, that he may be able to judge for himself. The celebrated Cassini, who discovered the rotation of Mars, Jupiter, and Venus, and four of the satellites of Saturn, was the first who broached this opinion. The following is his account of the observations on which it is founded:

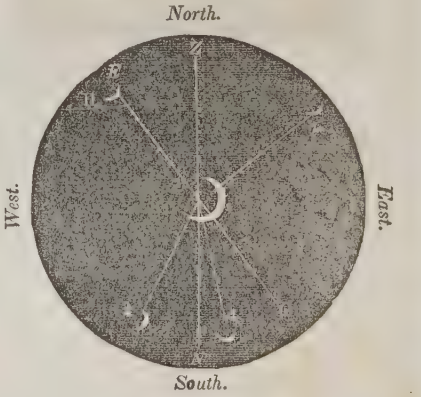
"1686, August 18, at fifteen minutes past four in the morning, looking at Venus with a telescope of thirty-four feet, I saw at the distance of three-fifths of her diameter, eastward, a luminous appearance, of a shape not well-defined, that seemed to have the same phase with Venus, which was then gibbous on the western side. The diameter of this phenomenon was nearly equal to a fourth part of the diameter of Venus. I observed it attentively for a quarter of an hour, and having left off looking at it for four or five minutes, I saw it no more; but daylight was then advanced. I had seen a like phenomenon, which resembled the phase of Venus, on January 25, 1672, from fifty-two minutes after six in the morning to two minutes after seven, when the brightness of the twilight caused it to disappear. Venus was then horned, and this phenomenon, the diameter of which was nearly a fourth part of the diameter of Venus, was of the same shape. It was distant from the southern horn of Venus, a diameter of Venus on the western side. In these two observations I was in doubt whether it was not a satellite of Venus, of such a consistence as not to be very well fitted to reflect the light of the sun, and which, in magnitude, bore nearly the same proportion to Venus as the moon does to the earth, being at the same distance from the sun and the earth as Venus was, the phases of which it resembled."

In the year 1740, October 23, at sunrise, Mr. Short, with a reflecting telescope of sixteen inches and a half, which magnified about sixty times, perceived a small star at the distance of about ten seconds from Venus; and, putting on a magnifying power of 240 times, he found the star put on the phase of Venus. He tried another magnifying power of 140 times, and even then found the star to have the same phase. Its diameter seemed about a third of the diameter of Venus. Its light was not so bright or vivid, but exceedingly sharp and well-defined. A line passing through the center of Venus and it made an angle with the equator of about twenty degrees. He saw it, for the space of an hour, several times that morning; but, the light of the sun increasing, he lost it about a quarter of an hour after eight. He says he looked for it every clear morning after this, but never saw it again.*

A similar phenomenon is described as having been seen by Baudouin, Montaigne, Rodkier, Montbarron, and other astronomers, and, from their observations, the celebrated M. Lambert, in the "Memoirs of the Academy of Berlin" for 1773, gave a theory of the satellite of Venus, in which he concludes that its period is eleven days, five hours, and thirteen minutes; the inclination of its orbit to the ecliptic, 63¾°; its distance from Venus, 66½ radii of that planet; and its magnitude, 4-27 of that of Venus, or nearly equal to that of our moon. There is a singular consistency in these observations, which it is difficult to account for if Venus have no satellite. Astronomers expected that such a body, if it existed, would be seen as a small dark spot upon the sun at the time of the transits of Venus in 1761 and 1769; but no such phenomenon seems to have been noticed at those times by any of the observers. Lambert, however, maintains, from the tables he calculated in relation to this body, that the satellite, if it did exist, might not have passed over the sun's disc at the time of the transits, but he expected that it might be seen alone on the sun when Venus passed near that luminary.

The following is a particular account of the observations made by Mr. Montaigne:—May 3, 1760, he perceived, at twenty minutes distance from Venus, a small crescent, with the horns pointing the same way as those of Venus. Its diameter was a fourth of that of its primary; and a line drawn from Venus to the satellite made, below Venus, an angle with the vertical of about twenty degrees toward the south, as in Fig 22, No. 3, where *Z N* represents the vertical, and *E C* a parallel to the ecliptic, making then an angle with the vertical of forty-five degrees The numbers 3, 4, 7, 11, mark the situations of the satellite on the respective days. May 4th, at the same hour, he saw the same star, distant from Venus about one minute more than before, and

Fig. 22.—No. 3.



---

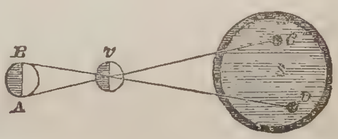
* "Philosophical Transactions," No. 459, for January February and March, 1741.

making an angle with the vertical of ten degrees below, but on the north side; so that the satellite seemed to have described an arc of about thirty degrees, whereof Venus was the center, and the radius twenty minutes. The two following nights being hazy, Venus could not be seen. But May 7th, at the same hour as on the preceding days, he saw the satellite again, but above Venus, and on the north side, as represented at 7, between twenty-five and twenty-six minutes, upon a line which made an angle of forty-five degrees with the vertical toward the right hand. It appears by the figure that the points 3 and 7 would have been diametrically opposite if the satellite had gone fifteen degrees more round the central point where Venus is represented. May 11th, at nine o'clock, P. M., the only night when the view of the planet was not obscured by moonlight, twilight, or clouds, the satellite appeared nearly at the same distance from Venus as before, making, with the vertical, an angle of forty-five degrees toward the south, and above its primary. The light of the satellite was always very weak; but it had always the same phase with its primary, whether viewed with it in the field of the telescope or alone by itself. He imagined that the reason why the satellite had been so frequently looked for without success might be, that one part of its globe was crusted over with spots, or otherwise unfit to reflect the light of the sun with any degree of brilliancy, as is supposed to be the case with the fifth satellite of Saturn.

It is evident that, if Venus have a satellite, it must be difficult to be seen, and can only be perceived in certain favorable positions. It cannot be seen when nearly the whole of its enlightened hemisphere is turned to the earth, on account of its great distance at such a time, and its proximity to the sun; nor could it be expected to be seen when the planet is near its inferior conjunction, as it would then present to the earth only a very slender crescent, beside being in the immediate neighborhood of the sun. The best position in which such a body might be detected is near the time of the planet's greatest elongation, and when it would appear about half enlightened. If the plane of its orbit be nearly coincident with the plane of the planet's orbit, it will be frequently hidden by the interposition of the body of Venus, and likewise when passing along her surface in the opposite point of its orbit; and if one side of this body be unfitted for reflecting much light, it will account in part for its being seldom seen. It is not sufficient in this case, to say, as Sir David Brewster has done, "that Mr. Wargentin had in his possession a good achromatic telescope, which always showed Venus with such a satellite, and that the deception was discovered by turning the telescope about its axis." For we cannot suppose that such accurate observers as those mentioned above would have been deceived by such an optical illusion; and, beside, the telescopes which were used in the observations alluded to were both refractors and reflectors, and it is not likely that both kinds of instruments would produce an illusion, especially when three different powers were applied, as in Mr. Short's observations. Were the attention of astronomers more particularly directed to this point than it has hitherto been; were the number of astronomical observers increased to a much greater degree than at present; and were frequent observations on this planet made in the clear and serene sky of tropical climes, it is not improbable that a decisive opinion might soon be formed on this point; and, if a satellite were detected, it would tend to promote the progress and illustrate the deductions of physical astronomy. It is somewhat probable, reasoning *a priori*, that Venus, a planet nearly as large as the earth, and in its immediate neighborhood, is accompanied by a secondary attendant.

Transits of Venus.—This planet, when in certain positions, is seen to pass like a round black spot across the disc of the sun. These *transits*, as they are called, are of rare occurrence, and take place at intervals of 8 and 113 years. If the plane of the orbit of Venus exactly coincided with that of the earth, a transit would happen at regular intervals of little more than nineteen months; but as one-half of this planet's orbit is three degrees and a half below the plane of the earth's orbit, and the other half as much above it, a transit can only take place when it happens to be in one of the *nodes*, or intersections of the orbits, about the time of its inferior conjunction. These transits of Venus are phenomena of very great importance in astronomy, as it is owing to the observations which have been made on them, and the calculations founded on these observations, that the distance of the sun has been very nearly ascertained, and the dimensions of the planetary system determined to a near approximation to the truth. It would be too tedious to enter into a particular explanation of the process and calculations connected with this subject, and, therefore, I shall only, in a few words, explain the *principle* on which the deductions are founded. Suppose *B A* (Fig. 23) to represent the earth; *v*, Venus; and *S* the sun. Suppose two spectators, *A* and *B*, at opposite extremities of that diameter of the earth which is perpendicular to the ecliptic; then, at the moment when the observer at *B* sees the center of the planet projected at *D*, the observer at *A* will see it projected at *C*. If, then, the two observers can mark the precise position of Venus on the sun's disc at any given moment, or note the precise time of ingress or egress of the planet, the angular measure of *C D*, as seen from the earth, might be ascertained. Since *A C* and *B D* are straight lines crossing each other at *v*, they consequently make equal angles on each side of the point *v*; and *C D* will be to *B A* as the distance of Venus from the sun is to her distance from the earth; that is, as 68 to 27, or nearly as 2½ to 1; for Venus is 68 millions of miles from the sun, and 27 millions from the earth, at the time of a transit or an inferior conjunction. *C D*, therefore, occupies a space on the sun's disc 2½ times as great as the earth's apparent diameter at the distance of the sun, or, in other words, it is equal to *five times* the sun's horizontal parallax; and, therefore, any error that might occur in measuring it will amount to only one-fifth of that error on the horizontal parallax that may be deduced from it; and it is on the ground of this parallax that the distance of the sun is determined. The result of all the observations made on the transits which happened in 1761 and 1769, gives about 8½ seconds as the horizontal parallax of the sun, which makes his distance 95 millions of miles. The distance is considered by the most enlightened astronomers as within *one-fiftieth* part of the true distance of

Fig. 23.



the sun from the earth; so that no future observations will alter this distance so as to increase or diminish it by more than two millions of miles.

The future transits of Venus for the next 400 years are as follows:

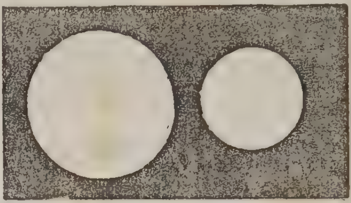
	Hours.	Minutes.
1874, December 9th........	4	8 A. M.
1882, December 6th........	4	16 P. M.
2004, June 8th............	8	51 A. M.
2012, June 6th............	1	17 A. M.
2117, December 11th.......	2	57 A. M.
2125, December 8th........	3	9 P. M.
2247, June 11th...........	0	21 P. M.
2255, June 9th............	4	44 A. M.

Some of these transits will last nearly seven hours. The next two transits will not be visible throughout their whole duration in Britain or in most countries in Europe. Such was the importance attached to the observations of the last transits, in 1761 and 1769, that several of the European states fitted out expeditions to different parts of the world, and sent astronomers with them, to make the requisite observations. This was one end, among others, of the celebrated expedition of Captain Cook, in 1769, to the islands of the Pacific Ocean; and the transit was observed in *Tahiti,* now so celebrated on account of the moral revolution which has lately taken place among its inhabitants.

Magnitude and Extent of Surface on this Planet.—The diameter of Venus has been computed at about 7800 miles; and, consequently, its surface contains 191,134,944, or above 191 millions of square miles. Taking, as formerly, the population of England as a standard, this planet would contain a number of inhabitants equal to more than 53,500 millions, or nearly sixty-seven times the population of our globe. It does not appear that any great quantity of water exists upon this planet, otherwise there would be a greater contrast between the different parts of its surface, the water presenting a much darker hue than the land. For, if from a high mountain we survey a scene in which a portion of a large river or of the ocean is contained, when the sun is shining on all the objects, we shall find that the water presents a much darker appearance than the land, as it absorbs the greater part of the rays of light, except in a few points between our eyes and the sun, where his rays are reflected from the surface of the fluid; but these partial reflections would be altogether invisible at the distance of the nearest planet. It is pretty evident, however, from what has been formerly stated, that there is a great diversity of surface on this planet; and if some of its mountains be more than twenty miles in elevation, they may present to view objects of sublimity and grandeur, and from their summits extensive and diversified prospects of which we can form no adequate conception. So that Venus, although a small fraction smaller than the earth, may hold a rank in the solar system, and in the empire of the Almighty, in point of population and sublimity of scenery, far surpassing that of the world in which we dwell.

Having dwelt so long on the phenomena of this planet, I shall state only the following additional particulars: The *quantity of light* on Venus is nearly twice as great as that on the earth, which will, doubtless, have the effect of causing all the colors reflected from the different parts of the scenery of that planet to present a more vivid, rich, and magnificent appearance than with us. It is probable, too, that a great proportion of the objects on its surface are fitted to reflect the solar rays with peculiar splendor; for its light is so intense as to be distinctly seen by telescopes in the day-time; and, during night, the eye is so overpowered by its brilliancy as to prevent its surface and margin from being distinctly perceived. Were we to indulge our imaginations on this subject, this circumstance might lead us to form various conceptions of the glory and magnificence of the diversified objects which may be presented to the view of the intellectual beings who inhabit this world; but, in the meantime, we have no sufficient *data* to warrant us in indulging in conjectural speculations. The apparent size of the sun as seen from Venus, compared with his magnitude as seen from the earth, is represented in fig. 24, the larger circle showing the size of the sun from Venus.

Fig. 24.



With regard to the *heat* in this planet, according to the principles and facts formerly stated (page 28), it may be modified by the constitution of its atmosphere and the nature of the substances which compose its surface, so that its intensity may not be so great as we might imagine from its nearness to the sun. Even on the supposition that the intensity of the heat of any body is inversely as the square of its distance from the sun, it has been calculated that the greatest heat in Venus exceeds the heat of St. Thomas, on the coast of Guinea, or of Sumatra, about as much as the heat in those places exceeds that of the Orkney Islands or that of the city of Stockholm; and, therefore, at 60 degrees north latitude on that planet, if its axis were perpendicular to the plane of its orbit, the heat would not exceed the greatest heat of the earth, and, of course, vegetation like ours could be carried on, and animals of a terrestrial species might subsist. But we have no need to enter into such calculations in order to prove the habitability of Venus, since the Creator has, doubtless, in this as well as in every other case, adapted the structure of the inhabitant, to the nature of the habitation.

In addition to the above, the following facts may be stated: Venus revolves in an orbit which is 433,800,000 of miles in circumference in the space of 224 days 16 hours; its rate of motion is therefore about eighty thousand miles every hour; one thousand three hundred and thirty miles every minute, and above twenty-two miles every second. Its distance from the sun is 68 millions of miles; and its distance from the earth, when nearest us, is about 27 millions of miles, which is the nearest approach that any of the heavenly bodies (except the moon) make to the earth. Yet this distance, when considered by itself, is very great; for it would require a cannon ball six years and three months to move from the earth to the nearest point of the orbit of Venus, although it were flying every moment at the rate of 500 miles an hour, or 12,000 miles a day. Were the enlightened hemisphere of the planet turned to the earth when it is in this nearest point of its orbit, it would appear like a brilliant moon, twenty-five times larger than it generally does to the nake eye; but at that time its light side is turned to the sun and away from the earth. At its greatest distance from us it is 163 millions of miles from the earth. The period of its *greatest brightness* is when it is about forty degrees from the sun, either before or after its inferior conjunction, at which time there is only about *one-fourth* part of its disc that appears enlightened. In this position it may sometimes be seen with the naked eye even amid the splendors of noonday. In the evening it casts a distinct shadow on a horizontal plane. Sir John Herschel remarks, that this shadow, to be distinguished, "must be thrown upon a white ground. An open window in a whitewashed room is the best exposure; in this situation I have observed not only the shadow, but the diffracted fringes edging its outline." The *density* of Venus compared with that of the sun is as 1 to 383,137, according to La Place's calculations, while that of the earth is as 1 to 329,630; so that the earth is somewhat denser than Venus. A body weighing one pound on the earth will weigh only 15 oz. 10 dr. on the surface of Venus. The *eccentricity* of the orbit of Venus is less than that of any of the other planets; it amounts to 492,000 miles, which is only the 1-276th part of the diameter of its orbit, which, consequently, approaches very nearly to a circle. The inclination of its orbit to the ecliptic is 3° 23′ 33″. Its mean apparent diameter is 17″, and its greatest about 57½″. Its greatest elongation from the sun varies from 45° to 47° 12′. Its mean arc of *retrogradation*, or when it moves from east to west, contrary to the order of the signs, is 16° 12′, and its mean duration forty-two days, commencing or ending when it is about 28° 48′ distant from the sun. Such is a condensed view of most of the facts in relation to Venus which may be considered as interesting to the general reader.

III. OF THE EARTH, CONSIDERED AS A PLANET.

In exhibiting the scenery of the heavens, it is not perhaps absolutely necessary to enter into any particular description of the earth; but as it is the only planetary body with which we are intimately acquainted, and the only standard by which we can form a judgment of the other planetary globes, and as it is connected with them in the same system, it may be expedient to state a few facts in relation to its figure, motion, structure, and general arrangements.

The earth, though apparently a quiescent body in the center of the heavens, is suspended in empty space, surrounded on all sides by the celestial luminaries and the spaces of the firmament. Though it appears to our view to occupy a space larger than all the heavenly orbs, yet it is, in fact, almost infinitely smaller, and holds a rank only with the smaller bodies of the universe; and, although it appears to the eye of sense immovably fixed in the same position, yet it is, in reality, flying through the ethereal spaces at the rate of more than a thousand miles every minute, as we have already demonstrated. The *figure* of the earth is now ascertained to be that of an oblate *spheroid*, very nearly approaching to the figure of a globe. An orange and a common turnip are oblate spheroids, and are frequently exhibited to illustrate the figure of the earth. But they tend to convey an erroneous idea; for, although a spheroid of ten feet diameter were constructed to exhibit the true figure of the earth, no eye could distinguish the difference between such a spheroid and a perfect globe, since the difference of its two diameters would scarcely exceed one-third of an inch; whereas, if its diameters bore the same proportion to each other as the two diameters of an orange generally do, its polar diameter would be nearly one foot three inches shorter than its equatorial.

Before the time of Newton, it was never suspected that the figure of the earth differed in any degree from that of a perfect sphere, excepting the small inequalities produced by the mountains and vales. The first circumstance which led to the determination of its true figure was an accidental experiment made with a pendulum near the equator. M. Richer, a Frenchman, in a voyage made to Cayenne, which lies near the equator, found that the pendulum of his clock no longer made its vibrations so frequently as in the latitude of Paris, and that it was absolutely necessary to shorten it in order to make it agree with the times of the stars passing the meridian. Some years after this, Messrs. Deshayes and Varin, who were sent by the French king to make certain astronomical observations near the equator, found that the pendulum at Cayenne made 148 vibrations less in a day than at Paris, and that his clock was retarded by that means two minutes twenty-eight seconds; and was obliged to make his pendulum shorter by two lines, or the sixth part of a Paris inch, in order to make the time agree with that deduced from celestial observations. Similar experiments, attended with the same results, were made at Martinique, St. Domingo, St. Helena, Goree, on the coast of Africa, and various other places, in all which it was found that the alteration was the greatest under the equator, and that it diminished as the observer approached the northern latitudes. This discovery, trifling as it may at first sight appear, opened a new field of investigation to philosophic minds; and there are, perhaps, few facts throughout the range of science from which so many curious and important facts have been deduced. Sir Isaac Newton and M. Huygens were among the first who perceived the extensive application of this discovery, and the important results to which it might lead. Newton, whose penetrating eye, traced the fact through all its bearings and remote consequences, at once perceived that the earth must have some other figure than what was commonly supposed, and demonstrated that this diminution of weight naturally arises from the earth's rotation round its axis, which, according to the laws of circular motion, repels all heavy bodies from the axis of motion; so that, this motion being swifter at the equator than in other parts more remote, the weight of bodies must also be less there than near the poles. All heavy bodies, when left to themselves, fall toward the earth in lines perpendicular to the horizon; and, were those lines continued, they would all pass through the earth's center. Every part of the earth, therefore, gravitates toward the center; and as this force is found to be about 289 times greater than that which arises from the rotation of the earth, a certain balance will constantly be maintained between them, and the earth will assume such a figure as would naturally result from the difference of these two opposite forces. From various considerations and circumstances of this kind, Newton founded his sublime calculations on this subject; and, as Fontenelle remarks, "determined the true figure of the earth without leaving his elbow-chair."

Newton and Huygens were both engaged in these investigations at the same time, unknown to each other, but the results of their calculations were nearly alike. They demonstrated, from the known laws of gravitation, that the true figure of the earth was that of an oblate spheroid, flattened at the poles, and protuberant at the equator; that the proportion between its polar and equatorial diameters is as 229 to 230, and, consequently, that the polar diameter is shorter than the equatorial by about thirty-four miles.* If these deductions be nearly correct, it follows that a degree of latitude in the polar regions must measure more than a degree near the equator. To determine this point by actual measurement, it was ordered by the French king that a degree should be measured both at the equator and within the polar circle. Messrs. Maupertuis, Clairaut, and others were sent to the north of Europe, and Messrs. Bouger, Godin, and La Condamine to Peru, in South America. The first of these companies began their operations at Tornea, near the Gulf of Bothnia, in July, 1736, and finished them in June, 1737. Those who were sent to Peru, having greater difficulties to encounter, did not finish their survey until the year 1741. The results of these measurements were, that a degree of the meridian in Lapland contains 344,627 French feet, and a degree of the meridian at the equator 340,606; so that a degree in Lapland is 4021 French feet, or 4280 English feet, longer than a degree at the equator; that is, they differ about six and a half English furlongs, or 8-10ths of a mile. But if the earth had been a perfect sphere, a degree of the meridian in every latitude would have been found precisely of the same length. This spheroidal figure is not peculiar to the earth; for the planets Saturn, Jupiter, and Mars are likewise found to be spheroids, and some of them much flatter at the poles than the earth. The difference between the polar and equatorial diameters of Jupiter is more than 6000 miles.

From the circumstances stated above, we may learn that the most minute facts connected with the system of nature ought to be carefully observed, investigated, and recorded, as they may lead to important conclusions, which, at first view, we may be unable to trace or to appreciate; for in the system of the material world, the greatest and most sublime effects are sometimes produced from apparently simple and even trivial causes. Who could have imagined that such a simple circumstance as the retardation of clocks in southern climes, and the shortening or lengthening of a pendulum, would lead to such an important discovery as the spheroidal figure of the earth? Hence we may conclude, that if ten thousands of rational observers of the facts of nature were to be added to those who now exist, many parts of the scenery of the universe which are now involved in darkness and mystery might ere long be unfolded to our view.

General Aspect of the Earth's Surface.—The most prominent and distinguishing feature of the surface of our globe is the two bands of *land* and of *water* into which it is divided. These bands present a somewhat irregular appearance and form, but their greatest length is from north to south. One of these bands of land, generally denominated the *eastern* continent, comprehends Europe, Africa, and Asia, and extends from the Cape of Good Hope on the south to the north-eastern extremity of Kamtschatka, in which direction its length measures about 10,000 miles.—Its greatest breadth from Corea, or the eastern parts of Chinese Tartary, to the western extremity of Africa, is about 9000 miles. The other band of earth is the *western* continent, comprehending North and South America, lying between the Atlantic on the east and the Pacific Ocean on the west. Its greatest length is about 8000 miles from north to south, and its greatest breadth, from Nootka Sound to Newfoundland, North America, and from Cape Blanco to St. Roque, South America, is about 3000 miles. Beside these two larger bands of land, there is the large island of New Holland, which is 2600 miles long and 2000 broad, which might be reckoned a third continent; along with many thousands of islands, of every form and size, which are scattered throughout the different seas and oceans. The whole of these solid parts of our globe comprehends an area of about forty-nine millions of square miles, or about one-fourth of the superficies of the terraqueous globe, which contains about one hundred and ninety-seven millions of square miles. Were all these portions of the land peopled with inhabitants in the same proportion as in England, the population of the globe would amount to thirteen thousand seven hundred and twenty millions of human beings, which is more than *seventeen* times its present number of inhabitants. Yet, strange to tell, this world has, in all ages, been the scene of wars, bloodshed, and contests for small patches of territory, although the one-seventeenth part of it is not yet inhabited!

There is a striking correspondence between two sides of the two continents to which we have adverted, the prominent parts of the one corresponding to the indentings of the other. If we look at a terrestrial globe or map of the world, we shall perceive that the projection of the western coast of Africa nearly corresponds with the opening between North and South America, opposite to the Gulf of Mexico; that the projection in South America, about Cape St. Roque and St. Salvador, nearly corresponds with the opening in the Gulf of Guinea; so that, if we could conceive the two continents brought into contact, the openings to which I have referred would be nearly filled up, so as to form one compact continent. The Gulf of Guinea would be nearly blocked up with the eastern coast of South America, and a large gulf formed between Brazil and the land to the eastward of the Cape of Good Hope. The Gulf of Mexico would be formed into a kind of inland lake, and Nova Scotia and Newfoundland would block up a portion of the Bay of Biscay and the English Channel, while Great Britain and Ireland would block up the entrance to Davis's Straits. A consideration of these circumstances renders it not altogether improbable that these continents were originally conjoined, and that, at some former physical revolution or catastrophe, they may have been rent asunder by some tremendous power, when the waters of the ocean rushed in between them, and left them separated as we now behold them. That POWER which is said to "remove mountains," which "shaketh the earth out of her place," and causeth "the pillars thereof to tremble," is adequate to produce such an effect; and effects equally stupendous appear to have been produced when the waters of the great deep covered the tops of the highest mountains, when the solid strata of the earth were bent and disrupted, and rocks of enormous size transported from one region of the earth to another. There appears no great improbability in the supposition that such an event may have taken place at the universal deluge, when the original constitution of the globe seems to have undergone a dreadful change and disarrangement.

---

* From a comparison of the length of different degrees of the meridian, lately measured, it is probable that the difference of the diameters is somewhat less than is here stated. Its equatorial diameter is about 7934 miles, and its polar about 7908.

Between the two continents now mentioned are two immense bands of water, extending nearly from the northern to the southern extremities of the globe, one of which is 10,000, and the other 3,000 miles broad. These vast collections of water surround the continents and islands, and form numerous seas, straits, gulfs, and bays, which indent and diversify the coasts through every region of the earth. They occupy a square surface of 148,000,000 of miles, forming about three-fourths of the surface of the globe, and containing about 296,000,000 of *cubical* miles of water, sufficient to cover the whole globe to the depth of 2600 yards. This vast superabundance of water, compared with the quantity of land, it is probable, is peculiar to our globe, and that no such arrangement exists on the surface of the other planets of our system. It is probable that such an extensive ocean did not exist at the period of the original formation of the earth, and that such a disproportionate accumulation of water took place in consequence of the deluge. The present constitution of the earth, and the disproportion of the water to the dry land, are circumstances more adapted to a race of fallen intelligences than to beings in a state of innocence, and adorned with the image of their Creator.

Beside the circumstances now stated, the earth is diversified with extensive ranges of mountains, which stretch in different directions along the continents and islands, rearing their summits, in some instances, several miles above the level of the ocean, and diversifying in various modes the landscape of the earth. From these mountains flow hundreds of majestic rivers, some of them more than 2000 miles in length, fertilizing the countries through which they flow, and forming a medium of communication between the inland countries and the ocean. The atmosphere is thrown around the whole of this terraqueous mass, by means of which, and the operation of the solar heat, a portion of the ocean is carried up to the region of the clouds in the form of vapor, which diffuses itself over every region of the earth, and is again condensed into rains and dews, to supply the sources of rivers, and to distribute fertility throughout every land. This atmosphere is the region of the *winds*, whether fanning the earth with gentle breezes, or heaving the ocean into mountainous billows, and overturning forests by hurricanes and tornadoes. It is the theater where thunders roll and lightnings flash, where the fiery meteor sweeps along with its luminous train, and where the *auroræ boreales* display their fantastic coruscations. It is constituted by a law of the Creator to sustain the principle of life, and to preserve in existence and in comfort not only man, but all the tribes of animated existence which traverse the regions of earth, air, or sea, without the benign influence of which this globe would be soon left without a living inhabitant.

Were the earth to be viewed from a point in the heavens, suppose from the moon, it would present a pretty variegated, and sometimes a mottled appearance. The distinction between its seas, oceans, continents, and islands would be clearly marked, which would appear like brighter and darker spots upon its disc. The continents would appear bright, and the ocean of a darker hue, because water absorbs the greater part of the solar light that falls upon it. The level plains (excepting, perhaps, such spots as the Arabian deserts of sands) would appear of a somewhat darker color than the more elevated and mountainous regions, as we find to be the case on the surface of the moon. The islands would appear like small bright specks on the darker surface of the ocean; and the lakes and Mediterranean seas like darker spots, or broad streaks intersecting the brighter parts of the land. By its revolution round its axis, successive portions of its surface would be brought into view, and present a different aspect from the parts which preceded. Were the first view taken when the middle of the Pacific Ocean appeared in the center, almost the whole hemisphere of the earth would present a dull and somber aspect, except a few small spots near the middle, where the Marquesas, the Sandwich, and the Society Isles are situated, and some bright streaks on its north-eastern, north-western, and south-western borders, where the north-western parts of America, the north-eastern parts of Asia and New Holland are situated. In about six hours afterward the whole of Asia, with its large islands, Borneo, Sumatra, New Guinea, &c., would come into view and diversify the scene, having a portion of the Pacific on the east, and the Indian Ocean and a portion of Africa on the west. In another six hours the whole of Africa and Europe, the Atlantic Ocean, and the eastern part of South America, would make their appearance; and in six hours more the whole of North and South America would appear near the center of the view, having the Atlantic Ocean on the east and the Pacific on the west. All these views would present a considerable variety of aspect, but in every one of them the darker shades would appear to cover the greater part of the view, except, perhaps, in that view which takes in the whole of Asia and part of Africa and Europe.— Each of these views occasionally present a mottled and unstable appearance, on account of the numerous strata of clouds suspended over different regions, which would be seen frequently to shift their positions. These clouds, when dense, and accumulated over particular countries, would prevent certain portions of the land and water from being distinctly perceived. They would sometimes appear like bright spots upon the ocean, by the reflection of the solar rays from their upper surfaces, and sometimes like dark spots over the land. The following figures represent two of the views to which we have alluded:

Fig. 25. Fig. 26.

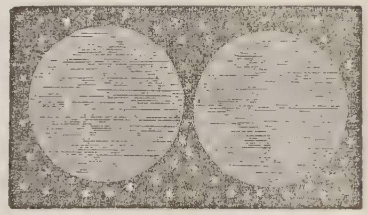


Fig. 25, represents the appearance of the earth when the middle of the Pacific is in the center of the view. Fig. 26, is the appearance when the Atlantic is presented to the spectator's eye, with South and part of North America on the west, and Europe, Africa, and a portion of Asia on the east.

Internal Structure of the Earth.—We are now pretty well acquainted with the general outline of the surface of the earth, and the different ramifications of land and water with which it is diversified, except those regions which lie adjacent to the poles. But our knowledge of its *internal* structure is extremely limited. The deepest mines that have ever been excavated do not descend above a mile from the surface, and this depth is no more, compared with the thickness of the earth, than the slight scratch of a pin upon a large artificial globe compared with the extent of its semidiameter. What species of materials are to be found two or three thousand miles within its surface, or even within fifty miles, will, perhaps, be forever beyond the power of mortals to determine. Various researches, however, have been lately made as to the materials which compose its upper strata, immediately beneath the surface, and the order in which they are arranged. From these researches we learn that substances of various kinds compose the exterior crust of the globe, and that they are thrown together in almost every possible position; some horizontal, some vertical, and some inclined to each other at various angles. Geologists have arranged the strata of the crust of the earth into various classes: 1. *Primary* rocks, which are supposed to have been formed before all the others, and which compose, as it were, the great frame or groundwork of our globe. These rocks are composed of *granite*, *gneiss*, *mica-slate*, and other substances; they form the most lofty mountains, and, at the same time, extend themselves downward beneath all the other formations, as if all the materials on the surface of the globe rested upon them as a basis. 2. *Transition* rocks, which are above the primitive, and rest upon them, and are composed of the larger fragments of the primary rocks, consolidated into continuous masses. These rocks contain the remains of certain organized beings, such as sea-shells, while no such remains are found among the rocks termed primitive. 3. *Secondary* rocks, which lie upon the primary and transition rocks, and which appear like deposits from the other species of rocks. The substances which this class of rocks contain are secondary limestone, coal, oolite, sandstone, and chalk. There are likewise *tertiary*, *basaltic*, and *volcanic* rocks, and *alluvial* and *diluvial* deposits. But it would be foreign to our present subject to descend into particulars.

From facts which have been ascertained respecting these and various other circumstances connected with the constitution of the earth, it has been concluded that important changes and astonishing revolutions have taken place in its physical structure since the period of its formation; that rocks of a huge size have been rolled from one region of the globe to another, and been carried up to the tops of hills and elevated portions of the land; that the hardest masses of its rocks have been fractured, and its strata bent and dislocated; that in certain places sea-shells, sharks' teeth, the bones of elephants, the hippopotamus, oxen, deer, and other animals, are found mingled together, as if they had been swept along by some overpowering force, amid a general convulsion of nature; that the bed of the ocean has been raised up by the operation of some tremendous power, so as to form a portion of the habitable surface of the globe; and that the loftiest mountains were once covered by the waters of the ocean. From these and other considerations we have reason to believe that the earth now presents a very different aspect from what it did when it first proceeded from the creating hand of its Maker, and when all things were pronounced by him to be "very good." The earth, therefore, as presently constituted, ought not to be considered as a standard or model to be compared with the other planets of our system, and by which to judge whether they appear to be fitted for being the abodes of intelligent beings. For, in its present state, notwithstanding the numerous objects of sublimity and beauty strewed over its surface, it can be considered as little more than a majestic ruin; a ruin, however, sufficiently accommodated to the character of the majority of inhabitants who have hitherto occupied its surface, whose conduct, in all ages, has been marked with injustice, devastation, and bloodshed.

Density of the Earth.—In the year 1773, Dr. Maskeline, the astronomer royal, with other gentlemen, made a number of observations on the mountain Schehallien, in Scotland, to determine the *attraction of mountains*. After four months spent in the necessary arrangements and observations, it was ascertained beyond dispute that the mountain exerted a *sensible* attraction, leaving no hesitation as to the conclusion that every mountain and every particle of earth is endowed with the same property in proportion to its quantity of matter. The observations were made on both sides of the mountain, and from these it appears that the sum of the two contrary attractions exerted upon the plumbline of the instruments was equal to eleven seconds and a half. Professor Playfair, more than thirty years afterward, from personal observation, endeavored to determine the specific gravity or density of the materials of which Schehallien is composed, and after numerous experiments and calculations, it was concluded that "the mean density of the earth is nearly double the density of the rocks which compose that mountain," which seem to be considerably more dense than the mean of those which form the exterior crust of the earth. The density of these rocks was reckoned to be two and a half times the weight of water; consequently the density of the earth is to that of water as five to one; that is, the whole earth, bulk for bulk, is *five times the weight of water*, so that the earth, as now constituted, would counterpoise five globes of the same size composed of the same specific gravity as water. As the mean density, therefore, of the whole earth's surface, including the ocean, cannot be above twice the density of water, it follows that the *interior* of the earth must have a much greater density than even five times the weight of water, to counterbalance the want of weight on its surface. Hence we are necessarily led to conclude that the interior parts of the earth, near the center, must consist of very dense substances, denser than even iron, lead, or silver, and that no great internal cavity can exist within it, as some theorists have supposed, unless we could suppose that most of the materials far below the foundation of the ocean are much denser than the heaviest metallic substances yet discovered. La Place has attempted to estimate the earth's density near the center on the following data: If 5 2-5 be its mean density, and 3 1-8, 3 1-5, 2 4-5, and 2 3-5 be assumed as its superficial densities, then, on the theory of compressibility, the density at the center will be 13¼, 14½, 15¾, and 20 1-10 respectively. The least of the specific gravities (13¼) is nearly double the density of zinc, iron, and the ore of lead; and the greatest (20 1-10) is nearly equal to purified and forged *platina*, which is the most ponderous substance hitherto discovered. Yet this ponderous globe, with all the materials on its surface, is carried through the regions of space with a velocity of sixteen hundred thousand miles every day.

Variety of Seasons.—The annual revolution of the earth is accomplished in 365 days, 5 hours, 48 minutes, and 51 seconds. In the course of this revolution, the inhabitants of every clime experience, though at different times, a variety of seasons. Spring, summer, autumn, and winter follow each other in constant succession, diversifying the scenery of nature, and distinguishing the different periods of the year. In those countries which lie in the southern hemisphere of the globe, November, December, and January, are the summer months, while in the northern hemisphere, where we reside, these are our months of winter, when the weather is coldest and the days are shortest. In the northern and southern hemispheres, the seasons are opposite to each other, so that when it is spring in the one it is autumn in the other; when it is winter in southern latitudes it is summer with us. During six months, from March 21 to September 23, the sun shines without intermission on the north pole, so that there is no night there during all that interval, while the south pole is all this time enveloped in darkness. From September to March the south pole enjoys the solar light, while the north, in its turn, is deprived of the sun and left in darkness. The sun is at different distances from the earth at different periods of the year, owing to the earth's moving in an elliptical orbit; but it is not upon this circumstance that the seasons depend. For on the first of January we are more than three millions of miles nearer the sun than on the first of July, when the heat of our summer is generally greatest. The true cause of the variation of the seasons consists in the inclination of the axis of the earth to the plane of its orbit; or, in other words, to the *ecliptic*. If its axis were *perpendicular* to the ecliptic, the equator and the orbit would coincide; and as the sun is always in the plane of the ecliptic, it would in this case be always over the equator; the two poles would be always enlightened, and there would be no diversity of days and nights, and but one season throughout the year. What is meant by the inclination of the axis will appear from the following figures.

Fig. 27.

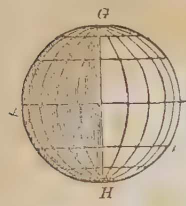

Fig. 28.

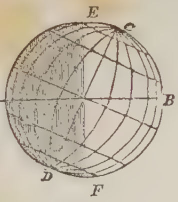


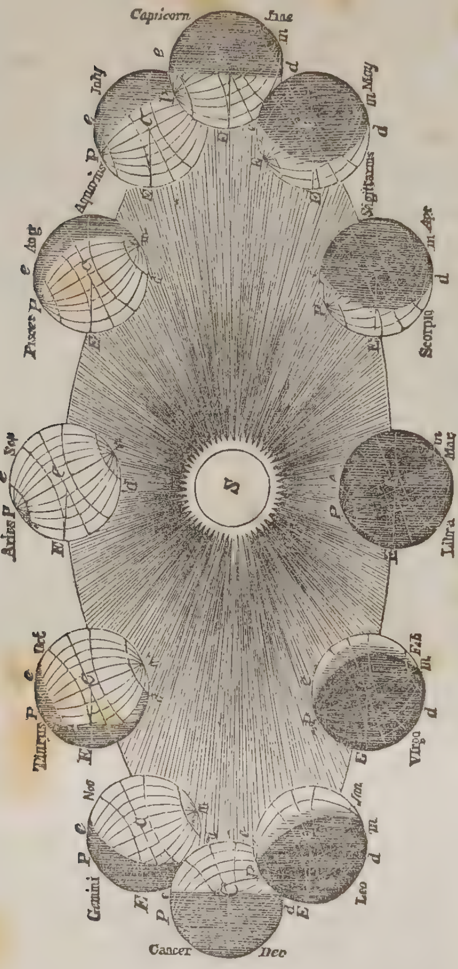
Let *A B* represent the plane of the ecliptic, or the earth's orbit, and *C D* (Fig 28) the axis of the earth, inclined at an angle of 66½° to the ecliptic, and 23½° from the perpendicular *E F*, or the axis of the ecliptic, and it will represent the position of the axis of the earth with respect to the plane of its orbit. Fig. 27 represents the axis of the earth, *G H*, *perpendicular* to the ecliptic. As the sun can enlighten only the one-half of the globe at a time, it is evident that, if his rays come in the direction from *B*, Fig. 28, they cannot illuminate both poles at once. While the north polar circle between *E* and *C* is enlightened, the regions around the south pole between *D* and *F* must necessarily remain in the dark. But if the axis of the earth were perpendicular to its orbit, as exhibited in Fig. 27, then both poles would constantly be enlightened at the same time. The following figure will more particularly show the effect of the inclination of the axis of the earth during its progress through the twelve signs of the zodiac. (See Fig. 29.)

In this representation the ellipse exhibits the earth's orbit seen at a distance, the eye being supposed to be elevated a little above the plane of it. The earth is represented in each of the twelve signs, with the names of the months annexed. In each of the figures *e* is the pole of the ecliptic, and *e d* its axis, perpendicular to the plane of the orbit. *P* is the north pole of the earth; *P m* its axis, about which the earth daily turns from west to east, *P C e* shows the angle of its inclination. During the whole of its course, the axis keeps always in a parallel position, or points always to the same parts of the heavens. If it were otherwise, if the axis of the earth shifted its position in any considerable degree, the most appalling and disastrous effects might be produced; the ocean in many places might overflow the land, and rush from the equator toward the polar regions, and produce a general devastation and destruction to myriads of its inhabitants. If the axis pointed always to the center of its orbit, so as to be continually varying its direction, all the objects around us would appear to whirl about us in confusion; there would be no fixed polar points to guide the mariner, nor could his course be directed through the ocean by any of the stars of heaven.

When the earth is in the first point of Libra, the sun appears in the opposite point of the ecliptic, at Aries, about the 21st of March; and when the earth is in Aries, the sun, *S*, will appear in Libra about the 23d of September. At these times both poles of the earth are enlightened, and the day and night are equal in all places. When the earth has moved from Libra to Capricorn, its axis keeping always the same direction, all places within the north polar circle, *P e*, are illuminated throughout the whole diurnal revolution, at which time the inhabitants of those places have the sun more than twenty-four hours above the horizon. This happens at the time of our summer solstice, or about the 21st of June, at which time the south polar circle, *d m*, is in darkness. While the earth is moving from Libra, through Capricorn, to Aries, the north pole, *P*, being in the illuminated hemisphere, will have six months continual day; but while the earth passes from Aries, through Cancer, to Libra, the north pole will be in darkness, and have continual night; the south pole at the same time enjoying continual day. When the earth is at Cancer, the sun appears at Capricorn, at which season the nights in the northern hemisphere will as much exceed the days as the days exceeded the nights when the earth was in the opposite point of its orbit.

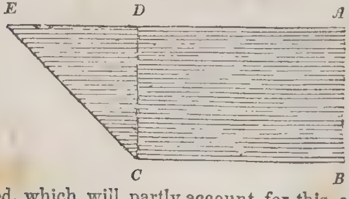
Our summer is nearly eight days longer than our winter. By summer is meant the time that passes between March 21 and September 23, or between the vernal and autumnal equinoxes; and by winter, the time between September 23 and March 21, the autumnal and vernal equinoxes. The portion of the earth's orbit which lies north of the equinoctial contains 184 degrees, while that portion which is south of the equinoctial contains only 176 degrees, being eight degrees less than the other portion, which is the reason why the sun is nearly eight days longer on the north of the equator than on the south. In our summer the sun's apparent motion is through the six northern signs, Aries, Taurus, Gemini, Cancer, Leo, and Virgo; and in our winter, through the six southern. In the former case, from March 21 to September 23, the sun is about 186 days 11 hours in passing through the northern signs, and only 178 days 18 hours in passing through the southern signs, from September 23 to March 21, the difference being about 7 days 17 hours. The reason of this difference is, that the earth moves in an elliptical orbit, one portion of which is nearer the sun than another, in consequence of which the sun's apparent motion is slower while it appears in the northern signs than while it traverses the southern ones.

Fig. 29.



As the sun is farther from us in summer than in winter, it may naturally be asked why we experience the greatest heats in the former season. The following, among other reasons, may be assigned, which will partly account for this effect: 1. The sun rises to a much higher altitude above the horizon in summer than in winter, and, consequently, its rays falling more directly and less oblique, the thicker or denser will they be, and so much the hotter, when no counteracting causes *from local circumstances* exist. Thus, supposing a parcel of rays, *A B C D E* (Fig. 30), to fall perpendicularly on any plane (*D C*), and *obliquely* on another plane (*E C*), it is evident they will occupy a smaller space (*D C*) in the former than (*E C*) in the latter; and, consequently, their heat would be much greater in the lesser space *D C* than in the greater space *E C*. If, instead of lines, we suppose *D C* and *E C* to be the diameters of surfaces, then the heat on those surfaces will be inversely as the squares of the diameters. Let *D C* be 20 and *E C* 28; the square of 20 is 400, and the square of 28 is 784, which is nearly double the square of *D C*, and, consequently, there is nearly double the quantity of heat on *D C* compared with that on *E C*, in so far as it depends on the *direct* influence of the solar rays; but other causes may concur either to diminish or increase the heat in certain places, to which I have already alluded when describing the phenomena of Mercury. 2. The greater length of the day contributes to augment the heat in summer; for the earth and the air are heated by the sun in the day-time, more than they are cooled in the night, and on this account the heat will go on increasing in the summer, and for the same reason will decrease in winter, when the nights are longer than the days. Another reason is, that in summer, when the sun rises to a great altitude, his rays pass through a much smaller portion of the atmosphere, and are less refracted and weakened by it than when they fall more obliquely on the earth, and pass through the dense vapors near the horizon.

Fig. 30.



The cause of the variety of the seasons can be exhibited with more clearness and precision by means of machinery than by verbal descriptions; and, therefore, those whose conceptions are not clear and well-defined on this subject, should have recourse to orreries and planetariums, which exhibit the celestial motions by wheel-work. There is a small instrument, called a *Tellurion*, which has been long manufactured by Messrs. Jones, Holborn, London, which conveys a pretty clear idea of the motions and phases of the moon, the inclination of the earth's axis to the plane of its orbit, and the changes of the seasons. It may be procured at different prices, from 1*l*. 8*s*. to 4*l*. 14*s*. 6*d*., according to the size and the quantity of the wheel-work.

The subject of the seasons and the variety of phenomena they exhibit have frequently been the themes both of the philosopher and the poet, who have expatiated on the beauty of the contrivance and the benignant effects they produce; and, therefore, they conclude that other planets enjoy the same vicissitudes and seasons similar or analogous to ours. But although, *in the present constitution of our globe*, there are many benign agencies which accompany the revolutions of the seasons, and are essential to our happiness in the circumstances in which we now exist, yet it is by no means probable that the seasons, *as they now operate*, formed a part of the original arrangements of our terrestrial system. Man was at first created in a state of innocence, and adorned with the image of his Maker; and the frame of nature, we may confidently suppose, was so arranged as to contribute in every respect both to his sensitive and intellectual enjoyment. But neither the horrors of winter, and its dreary aspect in northern climes, nor the scorching heats and appalling thunder-storms which are experienced in tropical climates, are congenial to the rank and circumstances of beings untainted with sin and endowed with moral perfection. Such physical evils and inconveniences as the change of seasons occasionally produces, appear to be only adapted to man in his present state of moral degradation. In the primeval state of the world, it is not unlikely that the axis of the earth had a different direction from what it has at present, and that, instead of scorching heats and piercing colds, and the gloom and desolations of winter, there was a more mild and equable temperature, and something approaching to what the poet calls "a perpetual spring." We are assured, from the records of sacred history, that the original constitution of the earth has undergone a considerable change and derangement: its strata were disrupted, "the fountains of the great deep were broken up," and a flood of waters covered the tops of the loftiest mountains; the effects of which are still visible in almost every region of the globe. At that memorable era, it is highly probable those changes were introduced which diversify the seasons and produce those alarming phenomena and destructive effects which we now behold; but as man advances in his moral, intellectual, and religious career, and in proportion as his mental and moral energies are made to bear on the renovation of the world, he has it in his power to counteract or meliorate many of the physical evils which now exist. Were the habitable parts of the earth universally cultivated, its marshes drained, and its desolate wastes reduced to order and vegetable beauty by the hand of art, and replenished with an industrious and enlightened population, there can be little doubt that the seasons would be considerably meliorated, and many physical evils prevented with which we are now annoyed. And all this is within the power of man to accomplish, provided he chooses to direct his wealth, and his intellectual and moral energies, into this channel. If these remarks have any foundation in truth, then we ought not to imagine that the earth is a standard by which we are to judge of the state of other planetary worlds, or that they are generally to be viewed as having a diversity of seasons similar to ours.

The following facts, in addition to the preceding, may be noted in relation to the earth: Under the equator, a pendulum, of a certain form and length, makes 86,400 vibrations in a mean solar day; but, when transported to London, the same pendulum makes 86,535 vibrations in the same time. Hence it is concluded that the intensity of the force urging the pendulum downward at the equator is to that at London as 86,400 to 86,535, or as 1 to 1.00315; or, in other words, that a mass of matter at the equator, weighing 10,000 pounds, exerts the same pressure on the ground as 10,031½ of the *same pounds* transported to London would exert there. If the gravity of a body at the equator be 1, at the poles it will be 1.00569, or about the 1-194th part heavier; that is, a body weighing 194 pounds at the equator would weigh 195 pounds at the north pole; so that the weight of bodies is increased as we advance from the equator to the poles, owing to the polar parts being nearer the center of the earth than the equatorial, and the centrifugal force being diminished. It is this variation of the action of gravity in different latitudes that causes the same pendulum to vibrate slower at the equator than in other places, as stated above. For a pendulum to oscillate seconds at the equator, it must be thirty-nine inches in length; and at the poles, thirty-nine and one-fifth inches.

The *tropical* year, or the time which the sun (or the earth) takes in moving through the twelve signs of the ecliptic, from one equinox to the same equinox again, is three hundred and sixty-five days, five hours, forty-eight minutes, and fifty-one seconds. This is the proper or natural year; because it always keeps the same seasons to the same months. The *sidereal* year is the space of time the sun takes in passing from any fixed star until it returns to the same star again. It consists of three hundred and sixty-five days, six hours, nine minutes, and eleven and a half seconds, being twenty minutes and twenty and a half seconds longer than the true solar year. This difference is owing to the regression of the equinoctial points, which is fifty seconds of a degree every year; and, to pass over this space, the sun requires twenty minutes and twenty and a half seconds. The earth moves in an elliptical orbit, whose *eccentricity*, or distance of its foci from the center, is 1,618,000 miles: that is, the ellipse or oval in which it moves is double the eccentricity, or 3,236,000 miles longer in one direction than it is in another, which is the reason that the sun is farther from us at one season of the year than at another. This is ascertained from the variation of the apparent diameter of the sun. About the first of January, when he is nearest the earth, the apparent diameter is thirty-two minutes, thirty-five seconds; and on the 1st of July, when he is most distant, it is only thirty-two minutes, thirty-one seconds. This proves that the earth has a slower motion in one part of its orbit than in another. In January, it moves at the rate of about 69,600 miles an hour, but in July its rate of motion every hour is only about 66,400 miles; a difference of more than 3000 miles an hour.

IV. OF THE PLANET MARS.

The earth is placed, in the solar system, in a position between the orbits of Venus and Mars. The two planets, Mercury and Venus, which are placed *within* the orbit of the earth, and whose orbits lie between it and the sun, are termed the *inferior* planets. Those whose orbits lie *beyond* the orbit of the earth, at a greater distance from the sun, as Mars, Jupiter, Saturn, and Uranus, are termed *superior* planets. The motions and aspects of all the superior planets, as seen from the earth, differ considerably from those which are exhibited by the inferior. In the first place, the inferior planets are never seen but in the neighborhood of the sun, none of them ever appearing beyond forty-eight degrees from that luminary; whereas, the superior planets appear at all distances from the sun, even in the opposite quarter of the heavens, or 180 degrees from the point in which the sun may happen to be placed. This could not possibly happen unless their orbits were *exterior* to that of the earth, and the earth placed at such times between them and the sun. In the next place, the inferior planets, when viewed through telescopes, exhibit, at different times, all the phases of the moon; but the superior planets never appear either horned or in the shape of a half moon. The planets Jupiter, Saturn, and Uranus, never appear in any other shape than *round*, or with full enlightened hemispheres. This circumstance of itself furnishes a proof that we see these planets always in a direction not very remote from that in which they are illuminated by the solar rays; and, consequently, that we occupy a station which is never very far removed from the center of their orbits. It proves, in other words, that the path of the earth round the sun is entirely included within their orbits, and likewise that this circular path of the earth *is of small diameter compared with their more expansive orbits.* This may be illustrated by the following figures. Let *S*, Fig. 32, represent the sun; *A B* the orbit of the earth; and *C* the planet Saturn, about ten times farther from the sun than the earth is. Suppose *B* to represent the earth at its greatest elongation from the sun, as seen from Saturn; the angle, *S C B*, being so small, it is evident that an observer on the earth, at *B*, can see little or nothing of the dark hemisphere of Saturn at *C*, but must perceive the whole enlightened hemisphere of the planet, within a small fraction, which fraction is not perceptible by our best telescopes

Fig. 31.

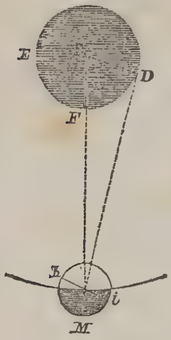


Fig. 32.

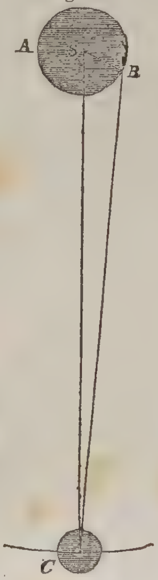

Fig. 33.

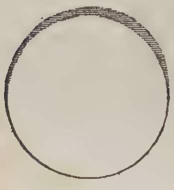
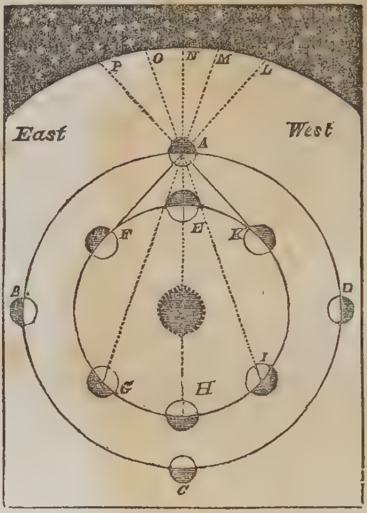


There is only one of the superior planets that exhibits any perceptible *phase,* and that is the planet *Mars.* In Fig. 31, *S* represents the sun; *E D*, the orbit of the earth; *M*, Mars; and *D*, the earth at its greatest elongation, as seen from Mars. In this case the angle *S M D* is much larger than in the former case, as Mars is much nearer to the earth than Saturn or any other of the superior planets. Consequently, a spectator on the earth is enabled to see a greater portion of the dark hemisphere of Mars, and, of course, loses sight of a corresponding portion of his enlightened disc.—This is represented by the line *h i*. This *gibbous* phase of Mars, however, differs only in a small degree from a circle; it is never less than seven-eighths of the whole disc. This phase is represented in Fig. 33. When the earth arrives near the point *F*, when Mars appears in opposition to the sun, the whole of his enlightened hemisphere is then visible. The extent of the gibbous phase of this planet affords a measure of the angle *S M D*, and, therefore, of the proportion of the distance, *S M* of Mars, to *S D* or *S F*, the distance of the earth from the sun, by which we are warranted to conclude that the *diameter of the orbit* of Mars cannot be less than 1 1-2 that of the orbit of the earth. The phases of Saturn, Jupiter, and Uranus being quite imperceptible, demonstrate that their orbits must include both the orbit of the earth and that of Mars; and, consequently, that they are removed at a much greater distance than either of these bodies from the center of the system.

Before proceeding to a particular description of the phenomena connected with the planet Mars, I shall give a brief sketch of the *motions* peculiar to this planet, which will serve, in some measure, as a specimen of the apparent motions of all the other superior planets. In the following figure *S* represents the sun; *A B C D* the planet Mars in four different positions in its orbit; *E F G H I K* the orbit of the earth; and *L M N O P*, a segment of the starry heavens. Suppose Mars at *A* and the earth at *E*, directly between it and the sun, then all the planet's enlightened hemisphere will be turned toward the earth, and it will appear like the full moon. When the planet is at *B* it will be *gibbous*, like the moon a few days before or after the full. At *C* it would again appear wholly enlightened, were it not in the same part of the heavens with the sun. At *D* it is again gibbous, as seen from *E*, and will appear less gibbous as it advances toward *A*. At *A* it is said to be in *opposition* to the sun, being seen from the earth at *E* among the stars at *N*, while the sun is seen in the opposite direction, *E C*. When the planet is at *C* and the earth at *E*, it is said to be in *conjunction* with the sun, being in the same part of the heavens with that luminary. In regard to all the superior planets, there is but *one* conjunction with the sun during the course of their revolution; whereas the inferior planets, Mercury and Venus, have *two* conjunctions, as formerly explained. Let us now attend to the *apparent* motions of this planet. Suppose the earth at *F*, and the planet at rest in its orbit at *A;* it will be projected or seen by a ray of light among the stars at *L;* when the earth arrives at *G*, the planet will appear at *M*, by the ray *G M;* and in the same manner, when the earth is at *H*, *I*, and *K*, the planet will be seen among the stars at *N*, *O*, and *P;* and, therefore, while the earth moves over the large part of its orbit, *F H K*, the

Fig. 34.



planet will have an apparent motion from *L* to *P* among the stars; and this motion is from west to east, in the order of the signs, or in the same direction in which the earth moves; and the planet is then said to be *direct* in motion. When the earth is at *K* and the planet appears at *P*, for a short space of time it appears *stationary*, because the ray of light proceeding from *P* to *K* nearly coincides with the earth's orbit and the direction of its motion. But when the earth moves on from *K* to *E*, the planet will appear to return from *P* to *N*; and while the earth moves from *E* to *F*, the planet will still continue to retrograde from *N* to *L*, where it will again appear stationary as before. From what has been now stated, it is clear, that since the part of the orbit which the earth describes in passing through *F H K* is much greater than the arc *K E F*, and the space *L P* which the planet describes in its direct and retrograde motion is *the same;* therefore, *the direct motion is very slow* from *L* to *P*, in comparison of the *retrograde motion* from *P* to *L*, which is performed in much less time.

In the above description I have supposed the planet at *rest* in its orbit at *A*, in order to render the explanation more easy and simple, and the diagram less complex than it would have been had we traced the planet through different parts of its orbit, together with the motions of the earth. But the appearances are the same, whether we suppose the planet to be at rest or in motion. The only difference is in the *time* when the retrograde or direct motions happen, and in *the places* of the heavens where the planet will be at such times situated. What has now been stated in regard to the apparent motions of Mars will apply to Jupiter, Saturn, and all the superior planets, making allowance for the difference of *time* in which their direct and retrograde motions are performed. All the superior planets are retrograde in their apparent motions when in *opposition*, and for some time before and after; but they differ greatly from each other, both in the extent of their *arc* of retrogradation, in the *duration* of their retrograde movement, and in its *rapidity*, when swiftest. It is more extensive and rapid in the case of Mars than of Jupiter, of Jupiter than of Saturn, and of Saturn than of Uranus. The longer the periodic time or annual revolution of a superior planet, the more frequent are its stations and retrogradations; they are less in quantity, but continue a longer time. The mean arc of retrogradation of Mars, or from *P* to *L*, Fig. 34, is sixteen degrees, twelve minutes, and it continues about seventy-three days; while the mean arc of retrogradation of Jupiter is only nine degrees, fifty-four minutes, but its mean duration is about 121 days. The time between one opposition of Saturn and another is 378 days, or one year and thirteen days. The time between two conjunctions or oppositions of Jupiter is 398 days, or one year and thirty-three days. But Mars, after an *opposition*, does not again come into the same situation until after two years and fifty days. It is only at and near the time of the opposition of Mars that we have the best telescopic views of that planet, as it is then nearest the earth; and, consequently, when it has passed its opposition for any considerable time, a period of two years must elapse before we see it again in such a conspicuous situation. Hence it is that this planet is seldom noticed by ordinary observers, except during a period of three or four months every two years. At all other times it dwindles to the apparent size of a small star.

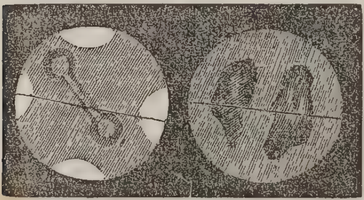
Distance, Motion, and Orbit of Mars.—This planet is ascertained to be about 145 millions of miles from the sun. From what we have stated above, it is obvious that, in the course of its revolution, it is at very different distances from the earth. When at its greatest distance, as when the earth is at *E*, and the planet at *C*, Fig 34, it is 240 millions of miles from the earth. This will appear from an inspection of the figure. The distance, *E S*, from the earth to the sun is 95 millions of miles; the distance, *S C*, of Mars from the sun is 145 millions. These distances, added together, amount to the whole distance from *E* to *C*, or from the earth to Mars when in conjunction with the sun. When nearest the earth, as at A, it is only 50 millions of miles distant from us. For as the whole distance of the planet from the sun, *A S*, is 145 millions, subtract the distance of the earth from the sun, *E S*=95 millions, and the remainder will be the distance of the planet, *E A*=50 millions of miles from the earth. Small as this distance may appear compared with that of some of the other planets, it would require more than 285 years for a steam-carriage, moving without intermission at the rate of twenty miles an hour, to pass over the space which intervenes between the earth and Mars at its nearest distance.

From what has been now stated, it is evident that this planet will present a very different aspect, as to size and splendor, in the different parts of its orbit. When nearest to the earth, it appears with a surface twenty-five times larger than it does at its greatest distance, and seems to vie with Jupiter in apparent magnitude and splendor. But, when verging toward its conjunction with the sun, it is almost imperceptible. And this is one proof, among others, of the truth of the Copernican system. All its motions, stations, and direct and retrograde movements, and the times in which they happen, exactly accord with its position in the system and the motion of the earth, as a planet between the orbits of Venus and Mars. Whereas, were the earth supposed to be the center of this planet's motion, according to the Ptolemaic hypothesis, it would be impossible to account for any of the phenomena above stated.

The orbit of Mars is 901,064,000, or more than 900 millions of miles in circumference. Through this space it moves in one year and 322 days, or in 16,488 hours. Consequently, its rate of motion is 54,640 miles every hour, which is more than a hundred times the greatest velocity of a cannon ball when it leaves the mouth of the cannon. The diurnal rotation of this planet, or its revolution round its axis, is accomplished in twenty-four hours, thirty-nine minutes, twenty-one seconds, which is about two-thirds of an hour longer than our day. This period of rotation was first ascertained by Cassini, from the motion of certain spots on its surface, which I shall afterward describe. Its axis is inclined to the plane of its orbit in an angle of thirty degrees, eighteen minutes, which is nearly seven degrees more inclined from the perpendicular than that of the earth. This motion is in the same direction as the rotation of the earth, namely, from west to east. The inclination of the orbit of Mars to that of the earth is one degree, fifty-one minutes, six seconds, so that this planet is never so much as two degrees either north or south of the ecliptic. The orbit of Mars is considerably *eccentric.* Its eccentricity is no less than 13,463,000 miles, or about 1-21 of its diameter, which is more than eight times the eccentricity of the orbit of the earth. Hence it follows, that Mars, when in opposition to the sun, may be nearer the earth by a considerable number of millions of miles at one time than at another, when he happens to be about his *perihelion*, or nearest distance from the sun at such opposition. On the 27th of August, 1719, this planet was in such a position, being in opposition within two and a half degrees of its perihelion, and nearer to the earth than it had been for a long period before; so that its magnitude and brightness were so much increased, that, by common spectators, it was taken for a new star.

Appearance of the Surface of Mars when viewed through Telescopes.—It was not before the telescope was brought to a certain degree of perfection that spots were discovered on the surface of Mars. This instrument was first directed to the heavens by Galileo, in the year 1610; but it was not until the beginning of 1666 that any of the spots which diversify this planet were discovered. On the 6th of February, that year, in the morning, Cassini, with a telescope of sixteen feet long, saw two dark spots on the face of Mars, as represented in Fig. 35; and on February 24, in the evening, he saw on the other face of the planet two other spots, somewhat like those of the first, but larger, as represented in Fig. 36.

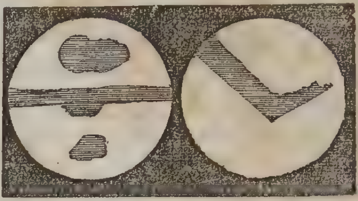
Fig. 35. Fig. 36.



These figures are copied from the first volume of the Transactions of the Royal Society. Afterward, continuing his observations, he found the spots of these two faces to turn by little and little from east to west, and to return at last to the same situation in which he had first seen them. Campani and several other astronomers observed similar spots about the same time at Rome, and Dr. Hook in England. Some of these observers were led to conclude, from the motion of these spots, that the rotation of this planet was accomplished in thirteen hours; but Cassini, who observed them with particular care, proved that the period of rotation was about twenty-four hours and forty minutes, and showed that the error of the other astronomers arose from their not distinguishing the difference of the spots which appeared on the opposite sides of the disc of Mars. The deductions of Cassini on this point have been fully confirmed by subsequent observations.

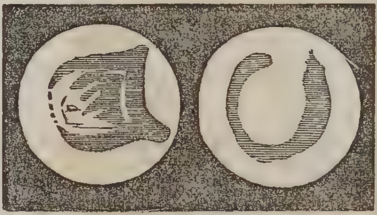
Maraldi, a celebrated French mathematician and astronomer, made particular observations on these spots in the year 1704. He observed that the spots were not always well-defined, and that they often changed their form, not only in the space of time from one opposition to another, but even within the space of a month; but some of them continued of the same form long enough to ascertain their periods. Among these was an oblong spot, not unlike one of the broken belts of Jupiter, that did not reach quite round the body of Mars, but had, not far from the middle of it, a small protuberance toward the north, so well-defined as to enable him to settle the period of its revolution at twenty-four hours, thirty-nine minutes; only one minute less than as Cassini had determined it. This appearance of Mars is represented in Fig. 37. On the 27th of August, 1719, the same observer, with a telescope of thirty-four feet in length, perceived, among several other spots, a long belt that reached about half way round the planet, not parallel to its equator, to the end of which another short belt was joined, so as to form an angle a little obtuse, as represented in Fig. 38.

Fig. 37. Fig. 38.



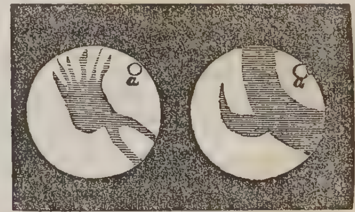
The following figures represent the appearance of the spots as seen by Dr. Hook in 1666. He saw Mars on March 3, 1666, as represented in Fig. 39, which appearance was taken down at the moment of observation. On the 23d of the same month he perceived the spots as delineated in Fig. 40, which appears to have been either the same spots in another position, or some other spots on the other hemisphere of the planet.

Fig. 39. Fig. 40.



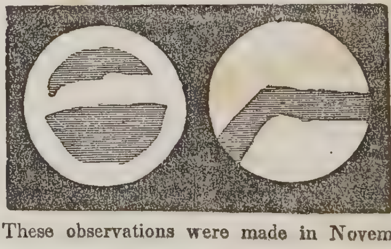
The following are two views of this planet by Sir William Herschel, who has given a great variety of delineations of the different appearances of Mars in the Transactions of the Royal Society of London for 1784.

Fig. 41 Fig. 42.



My own views of this planet have not been numerous, as it is only at intervals of two years, when near its opposition, that observations can be made on its surface with effect. I have, however, distinctly perceived its surface as delineated in Figures 43 and 44.

Fig. 43 Fig. 44.



These observations were made in November and December, 1832, and in January, 1837, and the appearances were very nearly the same; but the spots as represented in the two figures were seen at different times, and were evidently on different hemispheres of the planet, which were presented in succession by its motion of rotation. The instrument used in the observations was a 44½ inch achromatic telescope, with magnifying powers of 150 and 180 times.

Beside the dark spots here delineated, there is a small portion of the globe of Mars, round its south pole, which has, at least occasionally, a much brighter appearance than the other parts. Maraldi, who made observations on Mars about the year 1719, says, that this bright spot had been noticed for sixty years before that period, and that it is more permanent than any of the other spots of Mars; that this segment or zone is not all of equal brightness, more than one-half of it being brighter than the rest; that the part which is least bright is subject to great changes, and has sometimes disappeared; and that there has sometimes been seen a similar luminous zone round the north pole of Mars, which has appeared of different brightness in different years. The bright spot at the polar point is represented at *a*, Figures 41 and 42. These white spots have been conjectured to be snow, as they disappear when they have been long exposed to the sun, and are greatest when just emerging from the long night of the polar winter in that planet. This is the opinion of Sir W. Herschel, in his paper on this subject, in the Philosophical Transactions. "In the year 1781," says this astronomer, "the south polar spot was extremely large, which we might well expect, as that pole had but lately been involved in a whole twelve-month's darkness and absence of the sun; but in 1783, I found it considerably smaller than before, and it decreased continually from the 20th of May until about the middle of September, when it seemed to be at a stand. During this last period, the south pole had already been about eight months enjoying the benefit of summer, and still continued to receive the sunbeams, though, toward the latter end, in such an oblique direction as to be but little benefited by them. On the other hand, in the year 1781, the north polar spot, which had been its twelve-month in the sunshine, and was but lately returning into darkness, appeared small, though undoubtedly increasing in size." Hence he concludes, "that the bright polar spots are owing to the vivid reflection of light from frozen regions, and that the reduction of those spots is to be ascribed to their being exposed to the sun."

Atmosphere of Mars.—From the gradual diminution of the light of the fixed stars when they approach near the disc of Mars, it has been inferred that this planet is surrounded with an atmosphere of great extent. Although the extent of this atmosphere has been much overrated, yet it is generally admitted by astronomers that an atmosphere of considerable density and elevation exists. Both Cassini and Roemer observed a star, at six minutes from the disc of Mars, become so faint before it was covered by the planet, that it could not be seen even with a three feet telescope; which, in all probability, was caused by the light of the star being obscured by passing through the dense part of the atmosphere of the planet. It is, doubtless, owing to this circumstance that Mars presents so *ruddy* an appearance, more so than any other planet or star in the nocturnal sky. When a beam of light passes through a dense medium, its color inclines to red, the other rays being partly reflected or absorbed. Thus the morning and evening clouds are generally tinged with red, and the sun, moon, and stars, when near the horizon, either rising or setting, uniformly assume a ruddy aspect, because their light then passes through the lower and denser part of our atmosphere. When the light of the sun passes through the atmosphere of Mars, the most refrangible colors, such as the violet, will be partly absorbed; and before the reflected rays reach the earth, they must again pass through the atmosphere of the planet, and be deprived of another portion of the most refrangible rays; and, consequently, the red rays will predominate, and the planet assume a dull red color. This I conceive to be the chief reason why I could never perceive Mars in the day-time, even when in the most favorable position, so distinctly as Jupiter, although the quantity of solar light which falls on this planet is more than eleven times greater than what falls on Jupiter; which seems to indicate that Jupiter is surrounded with a less dense and more transparent atmosphere. Sir W. Herschel, though he questions the accuracy of some of the observations of the dimness caused by the appulses of the fixed stars to this planet, yet admits that it has a considerable atmosphere. "For," says he, "beside the permanent spots on its surface, I have often noticed occasional changes of partial bright belts, and also once a darkish one in a pretty high latitude: and these alterations we can hardly ascribe to any other cause than the variable disposition of clouds and vapors floating in the atmosphere of the planet."

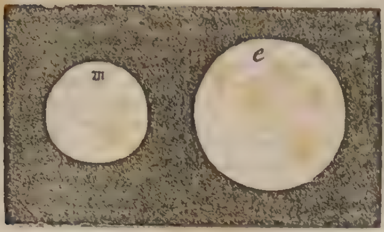
Conclusions respecting the Physical Constitution of Mars.—From the preceding observations and views we have exhibited of this planet, I presume we are warranted to deduce, with a high degree of probability, the following conclusions: 1. That land and water, analogous to those on our globe, exist in the planet Mars. The dark spots are obviously the water or seas upon its surface, which reflect a much less proportion of the solar light than the land. "The seas," says Sir John Herschel, "by a general law in optics, appear *greenish*, and form a contrast to the land. I have noticed this phenomenon on many occasions, but never more distinct than on the occasion when the drawing was made;" from which the figure of Mars in his "Astronomy" is engraved. It is not improbable, from the size of the dark spots compared with the whole disc of Mars, that about one-third or one-fourth of the surface of that planet is covered with water. If this estimate be nearly correct, it will follow that the quantity of land and water on Mars is nearly in a reverse proportion to that which obtains on our globe, where the quantity of water is nearly four times greater than that of the land. The dark spots in some of the views given above seem to convey the idea of several large gulfs or bays running up into the land. The various appearances of these spots which we have delineated are partly owing to the different relations and positions in which they appear during different periods of the planet's rotation, as I have already shown, would happen in the appearance of the earth were it viewed from a distance in the heavens (see page 41). 2. It is probable, too, that there are strata of clouds of considerable extent occasionally floating in the atmosphere of Mars; for some of the observers referred to above have remarked that some of the spots "changed their form in the course of a month;" and Sir W. Herschel, as above stated, declares that he has noticed "occasional changes of partial bright belts, and also once of a darkish one." These, in all probability, were clouds of greater or less density, which, for the most part, would appear brighter than the seas by the reflection of the solar rays from their upper surfaces; for although the *under* surface of dense clouds appears dark to us who view them from below, yet, were we to view their upper surface from a distance when the sun shines upon them, they would undoubtedly present a bright appearance by the reflection of the solar rays. It is, doubtless, owing to the occasional interposition of such clouds in the atmosphere of Mars, that the *permanent* spots sometimes appear to vary their form and aspect. 3. A variety of seasons, somewhat similar to ours, must be experienced in this planet. The diversity of seasons on our globe arises chiefly from the inclination of its axis to the plane of the ecliptic. Now, in reference to Mars, the axis of rotation is inclined to its orbit at even a greater angle than that of the earth; and, therefore, the contrast between its opposite seasons is probably more marked and striking than on the earth. The seasons will also continue for a much longer period than with us, as the year in Mars is nearly double the length of ours, so that summer and winter will be prolonged for a period of eight or nine months respectively. If the opinion of Sir W. Herschel be correct, that the white spots at the poles of Mars are caused by the reflection of the sun's rays from masses of ice and snow, it will afford an additional proof of the existence of a diversity of seasons on this planet, and that its inhabitants are subjected to a winter of great severity and of long duration. 4. This planet bears a more striking resemblance to the earth than any other planet in the solar system. Its distance from the sun, compared with that of the other superior planets, is but a little more than that of the earth. The distinction of land and water on its surface is more strikingly marked than on any of the other planets. It is encompassed with an atmosphere of considerable extent. It is probable that large masses of clouds are occasionally formed in that atmosphere, such as sometimes hover over the whole of Britain, and even of Europe, for several weeks at a time. The length of the day is nearly the same as ours, and it has evidently a succession of different seasons. Were we warranted from such circumstances to form an opinion respecting the physical and moral state of the beings that inhabit it, we might be apt to conclude that they are in a condition not altogether very different from that of the inhabitants of our globe.

Magnitude and Extent of Surface of Mars.—This planet is now estimated to be about 4200 miles in diameter, which is only a little more than half the diameter of the earth. It contains 38,792,000,000 or more than 38 thousand millions of solid miles; and the number of square miles on its surface is 55,417,824, or more than fifty-five millions, which is about six millions of square miles more than on all the habitable parts of our globe. At the rate of population formerly stated, 280 to a square mile, it would contain a population of more than fifteen thousand five hundred millions, which is nineteen times the number of the inhabitants of the earth, but, as it is probable that one-third of the surface of Mars is covered with water, should we subtract one-third from these sums, there would still remain accommodation for twelve times the number of the population of our globe.

No *moon* or secondary planet has yet been discovered about Mars; yet this is no proof that it is destitute of such an attendant; for as all the secondary planets are much less than their primaries, and as Mars ranks among the smallest planets of the system, its satellite, if any exist, must be extremely small. The second satellite of Jupiter is only the 1-43d part of the diameter of that planet; and a satellite bearing the same proportion to Mars would be only ninety-seven miles in diameter. But, suppose it were double this size, it could scarcely be distinguishable by our telescopes, especially when we consider that such a satellite would never appear to recede to any considerable distance from the margin of Mars. The distance of the first satellite of Jupiter is only three diameters of that planet from its center; and the distance of the first satellite of Saturn is but one diameter and two-thirds from its center. Now, if a satellite of the size we have supposed were to revolve round Mars at the distance of only two or three of its diameters, its nearness to the body of Mars would generally prevent its being perceived, unless with telescopes of very great power and under certain favorable circumstances; and it could never be expected to be seen but about the time of that planet's opposition to the sun, which happens only at an interval of more than two years. If such a satellite exist, it is highly probable that it will revolve at the nearest possible distance from the planet, in order to afford it the greatest quantity of light; in which case it would never be seen beyond two minutes of a degree from the margin of the planet, and that only in certain favorable positions. If the plane of its orbit lay nearly in a line with our axis of vision, it would frequently be hidden either by the interposition of the body of Mars or by transiting its disc. It is therefore possible, and not at all improbable, that Mars may have a satellite, although it has not yet been discovered. It is no argument for the non-existence of such a body that we have not yet seen it; but it ought to serve as an argument to stimulate us to apply our most powerful instruments to the regions around this planet with more frequency and attention than we have hitherto done, and it is possible our diligence may be rewarded with the discovery. The long duration of winter in the polar regions of Mars seems to require a moon to cheer them during the long absence of the sun; and if there be none, the inhabitants of those regions must be in a far more dreary condition than the Laplanders and Greenlanders of our globe

Proportion of Light on the Surface of Mars.—As the quantity of solar light on any of the planets is in an inverse proportion to their distances from the sun, the quantity of light which falls upon Mars will be much less than that which we enjoy. It is nearly in the proportion of 43 to 100, which is less than one-half of the light which falls upon the earth. This is partly the reason why Mars appears so much less brilliant than Venus, but it is not the only reason; for Jupiter appears much more brilliant than Mars, although he is placed at a much greater distance from the sun. The refraction, reflection, and absorption of the rays of light, in passing through the dense atmosphere to which we have alluded, form, doubtless, one principal reason why Mars appears more somber in its aspect than Jupiter or Venus The following figure represents the apparent size of the sun as seen from Mars and the earth. The circle *m* represents the size of the sun as seen from Mars, and *e* as seen from the earth. The degree of *heat* on different parts of this planet will depend upon various circumstances; the inclination of its axis, the positions of places in respect to its equator and poles, the nature of its soil, the materials which compose its surface, the quantity of

Fig. 15.



water in different regions, the constitution of its atmosphere, and other circumstances with which we are unacquainted.

The *figure* of Mars is an *oblate spheroid*, like that of the earth, but much flatter at the poles.—Its equatorial diameter is to its polar as 1355 to 1272, or nearly as 16 to 15; consequently, if its equatorial diameter be 4200 miles, its polar diameter will be only 3937, which is 263 miles shorter than the equatorial. The *mass* of this planet compared with that of the sun is as 1 to 1,846,082. Its *density*, compared with water, is as 3 2-7 to 1, which is considerably less than that of the earth, but greater than the general density of the rocks and other materials which compose the surface of our globe. A body which weighs one pound on the surface of the earth would weigh only five ounces six drachms on the surface of Mars.

V. ON THE LATELY-DISCOVERED PLANETS, VESTA, JUNO, CERES, AND PALLAS.

The immense interval which lies between the orbits of Mars and Jupiter led some astronomers to surmise that a planet of considerable magnitude might possibly exist somewhere within this limit. This conjecture was grounded on the intervals which exist between the rest of the planetary orbits. Between the orbits of Mercury and Venus there is an interval of 31,000,000 of miles; between those of Venus and the earth, 27,000,000; between those of the earth and Mars, 50,000,000; but between the orbits of Mars and Jupiter there intervenes the immense space of 349,000,000 of miles. Here the order of the solar system was supposed to be interrupted, which would form an exception to the general law of the proportion of the planetary distances. No planetary body, however, was detected within this interval until the beginning of the present century; and, instead of one large body, as was surmised, four very small ones have been discovered. These bodies are situated at a distance from Mars nearly corresponding to the order and proportion to which we have now alluded; and this circumstance leads to a belief "that it is something beyond a mere accidental coincidence, and belongs to the essential structure of the system." As these bodies are invisible to the naked eye, and can only be seen in certain favorable positions, and as only a short period has elapsed since their discovery, we are not yet much acquainted with many of their phenomena and physical peculiarities.

Of these four bodies, the first discovered was that which is now named *Ceres*, and sometimes *Piazzi*, from the name of its discoverer. It was discovered at Palermo, in the island of Sicily, on the 1st of January, 1801, or the first day of the present century, by Piazzi, a celebrated astronomer belonging to that city, who has since distinguished himself by his numerous observations on the fixed stars. This new celestial body was then situated in the constellation Taurus, and, consequently, at no very great distance from its opposition to the sun. It was observed by Piazzi until the 12th of February following, when a dangerous illness compelled him to discontinue his observations; but it was again discovered by Dr. Olbers, of Bremen, after a series of unwearied observations and laborious calculations, founded on a few insulated facts which had been stated by Piazzi. Dr. Brewster states, in the "Edinburgh Encyclopædia," vol. ii, p. 638, and likewise in his second edition of "Ferguson's Astronomy," vol. ii, p. 38, "that the rediscovery of this planet by Olbers did not take place until the 1st of January, 1807;" which must be a mistake, for in "*La Decade Philosophiques*," for July, 1803, it is stated that Dr. Olbers, some time before, received La Lande's prize for having discovered the planet Pallas; and, at the same time, his merit is referred to in having rediscovered Ceres; and having been among the first that announced it to the world. Beside, Sir W. Herschel has observations on this planet in the "Philosophical Transactions," of date February 7, 1802, which, of course, was posterior to Dr. Olbers' rediscovery.

The planet *Pallas*, or, as it is sometimes named, *Olbers*, was discovered on the 28th of March, 1802,—only fifteen months after the discovery of Ceres,—by Dr. Olbers, a physician at Bremen, in Lower Saxony, distinguished for his numerous celestial observations, and for his easy and commodious method of calculating the orbits of comets. The planet *Juno* was discovered on the evening of September 1, 1804, within two years and a half of the discovery of Pallas, by M. Harding, at the observatory of Lilienthal, near Bremen, while endeavoring to form an atlas of all the stars near the orbits of Ceres and Pallas, with the view of making further discoveries. While thus engaged, he perceived a small star of about the eighth magnitude, which was not marked in the Celestial Atlas of La Lande, which he put down in his chart. Two days afterward he found that the star had disappeared from the position in which he had marked it; but a little to the south-west of that position he perceived another star resembling it in size and color; and having observed it again on the 5th of September, and finding that it had moved a little in the same direction as before, he concluded that it was a moving body connected with the solar system.

The planet *Vesta* was discovered on the 29th of March, 1807, little more than two years and a half after the discovery of Juno, so that four primary planets belonging to our system, which had been hidden for thousands of years from the inhabitants of our globe, were discovered within the space of little more than six years.—Vesta must then have been near its opposition. The discovery of Vesta was made by Dr. Olbers, who had previously discovered Pallas, and rediscovered Ceres. He had formed an idea that the three small bodies lately discovered might possibly be the fragments of a larger planet, which had been burst asunder by some unknown and powerful irruptive force proceeding from its interior parts, and that more fragments might still be detected. Whether this position be tenable or not, it seems to have led to the discovery of Vesta; for the doctor concluded, if his opinions were just, that although the orbits of all these fragments might be differently inclined to the ecliptic, yet, *as they must all have diverged from the same point*, "they ought to have two common points of reunion, or *two nodes in opposite regions of the heavens*, through which all the planetary fragments must sooner or later pass." One of these nodes, or points of intersection of the orbits he found to be in the sign *Virgo*, and the other in the constellation of the *Whale;* and it was actually in the regions of the Whale that the planet Juno was discovered by M. Harding. With the view, therefore, of detecting other fragments, if any should exist, Dr. Olbers examined, three times every year, all the small stars in the opposite constellations of Virgo and the Whale, and in the constellation of *Virgo* the planet Vesta was first seen.[*] This was doubtless a remarkable coincidence of theory with observation, and affords a presumption that the conjecture of this eminent astronomer may possibly have a foundation in fact.

The following is a summary of what has been ascertained respecting the distances, magnitudes, and motions of these bodies:

The Planet Vesta.—The mean distance of this planet from the sun is reckoned to be about 225 millions of miles; its annual revolution is completed in about 3 years 7½ months, or in 1325 days; the circumference of its orbit is 1414 millions of miles, and, of course, it moves with a velocity, on an average, of more than 44,000 miles an hour. The inclination of its orbit to the plane of the ecliptic is seven degrees, eight minutes; and its eccentricity 21 millions of miles. The diameter of this planet has been estimated by some astronomers at only about 270 miles; and, if this estimate be correct, it will contain only 229,000 square miles, or a surface somewhat less than Great Britain, France, and Ireland; and, according to the rate of population formerly stated, would contain 64 millions of inhabitants, or about five times the number of the inhabitants of the United States of America, or nearly the twelfth part of the population of the earth. It is probable, however, that this estimate is too small, and that the apparent diameter of this planet has not yet been accurately taken; for the light of this body is considered equal to that of a star of the fifth or sixth magnitude, and it may sometimes be distinguished, in a clear evening, by the naked eye. Its light is more intense and white than that of either Ceres, Juno, or Pallas; and it is not surrounded with any nebulosity, as some of these planets are. It is not likely that a body of this size could be seen at the distance of 130 millions of miles, which is its nearest approach to the earth, and that, too, by the naked eye (as Schroeter affirms he did several times), unless the substances on its surface were of such a nature as to reflect the solar rays with a far greater degree of brilliancy than any of the other planets. The diameter of the third satellite of Jupiter is reckoned at 3377 miles, and its surface, of course, contains 35,827,211 square miles, which is 156 times greater than the *surface* of Vesta, according to the above estimation. Yet this satellite can never (or, at least, but rarely) be seen by the naked eye. Vesta is, indeed, only about one-third the distance from us of the satellite of Jupiter; but, making allowance for this circumstance, it should be at least twenty times larger *in surface* than is estimated above in order to be seen by the naked eye, or with the same distinctness as the third satellite of Jupiter. In other words, it should have a diameter of at least 1200 miles. If this is not the case, there must be something very peculiar and extraordinary in the reflective power of the materials which compose its surface to produce such an intensity of light from so small a body at so great a distance as 130 millions of miles. I am therefore of opinion that the size of this planet has not yet been accurately ascertained, and that future and more accurate observations are still requisite to determine its apparent diameter and real magnitude.

The Planet Juno.—The next planet in the order of the system is Juno. Its distance from the sun is estimated at 254 millions of miles. The circumference of its orbit is 1596 millions of miles. Through this circuit it moves in four years and 128 days, at the rate of 41,850 miles every hour. Its diameter, according to the estimate of Schroeter, is 1425 English miles. Its surface will therefore contain six millions, three hundred and eighty thousand square miles, and a population of one thousand, seven hundred and eighty-six millions, which is more than double the number of the earth's inhabitants. The orbit of Juno is inclined to the ecliptic in an angle of thirteen degrees, three minutes. Its eccentricity is 63,588,000 miles, so that its greatest distance from the sun is 316,968,000 miles, while its least distance is only 189,792,000. Its apparent diameter as seen from the earth is little more than three seconds. This planet is of a reddish color, and is free from any nebulosity; yet the observations of Schroeter render it probable that it has an atmosphere more dense than that of any of the old planets of the system. A remarkable variation in the brilliancy of this planet has been observed by this astronomer, which he attributes to changes that are going on in its atmosphere, and thinks it not improbable that these changes may arise from a diurnal rotation performed in twenty-seven hours.

The Planet Ceres.—This planet is about 263 millions of miles from the sun, and completes its annual revolution in four years, seven months, and ten days. The circumference of its orbit is 1653 millions of miles, and it moves at the rate of about forty-one thousand miles an hour. The eccentricity of its orbit is 20,598,000 miles. Its greatest distance from the sun is 283,500,000 miles, and its least distance 242,300,000. Its apparent mean diameter, including its atmosphere, according to Schroeter, is somewhat more than six seconds at its mean distance from the earth

---

[*] William Olbers, M. D., the discoverer of Vesta and Pallas, was born on the 11th of October, 1758, at Arbergen, a village in the Duchy of Bremen, where his father was a clergyman. His father, beside being a man of great general learning, was a good mathematician and a lover of astronomy. Young Olbers, when in his fourteenth year, felt a great taste for that science. During an evening walk in the month of August, having observed the Pleiades, or seven stars, he became very desirous of knowing to what constellation they belonged. He therefore purchased some charts and books, and began to study this science with the greatest diligence; he read with the greatest avidity every astronomical work he was able to procure, and in a few months made himself acquainted with all the constellations. Finding that a knowledge of mathematics was necessary to the study of astronomy, he devoted all his leisure time to this subject. He was at the same time engaged in the study of medicine as a profession. In the year 1779, when scarcely twenty-one years of age, he observed at Gottingen, and calculated the first comet. An account of this labor was published in the "Berlin Astronomical Calendar" for 1782, where it is mentioned that Olbers made his construction one night while attending a patient; and yet it was afterward found that his determination of this orbit corresponded with the most accurate elements of the comet which were calculated. Since that period, the astronomy of comets has been his favorite study, and it is admitted that none of the methods formerly tried for calculating the orbit of a comet is so simple, and, at the same time, so elegant as that of Dr. Olbers. When at Vienna, amid all his applications to the study of medicine, he was the first who observed the planet Uranus (after its discovery by Herschel), on the 17th of August, 1781. On the 19th he perceived its motion, and continued his observations until the end of September, at which period it was considered as a comet. Returning from the scene of his studies, he settled at Bremen as a physician, where he soon acquired the confidence of his fellow-citizens, both on account of his successful practice and integrity and affability of his character.

Its real diameter, according to the estimate of the same astronomer, is 1624 English miles; but, including its atmosphere, is 2974 miles. Its surface, therefore, contains 8,285,580 square miles, or about the one-sixth part of the habitable portions of our globe; and would afford accommodation for 2,319,962,400, or more than 2300 millions of inhabitants, according to the rate of population in England, which is nearly triple the present population of the earth. This planet is of a slight ruddy color, and appears about the size of a star of the eighth magnitude, and is consequently invisible to the naked eye. It seems to be surrounded with a dense atmosphere, and exhibits a disc or sensible breadth of surface when viewed with a magnifying power of two hundred times. Schroeter has determined, from a great number of observations, that its atmosphere is about six hundred and seventy-five English miles in hight, and that it is subject to numerous changes. Like the atmosphere of the earth, it is very dense near the planet, and becomes rarer at a greater distance, which causes its apparent diameter to appear somewhat variable. When this planet is approaching the earth, toward the point of its opposition to the sun, its diameter increases more rapidly than it ought to do from the diminution of its distance, which Schroeter supposes to arise from the finer exterior strata of its atmosphere becoming visible while it approaches the earth. He also perceived that the visible hemisphere of the planet was sometimes overshadowed, and at other times cleared up, so that he concludes there is little chance of discovering the period of its diurnal rotation. The inclination of its orbit to the ecliptic is in an angle of ten degrees, thirty-seven minutes. The intensity of light upon its surface is more than seven times less than what we enjoy.

Sir William Herschel, in the year 1802, after the discovery of Ceres and Pallas, made a number of observations to ascertain if any of these bodies were accompanied with satellites. Several very small stars were occasionally perceived near Ceres with high magnifying powers, of the positions and motions of which he has given several delineations; but it did not appear probable, in subsequent observations, that they accompanied the planet. In his observation of April 28, with a power of 550, he says, "Ceres is surrounded with a strong haziness. The breadth of the coma, beyond the disc, may amount to the extent of a diameter of the disc, which is not very sharply defined. Were the whole coma and star taken together, they would be at least three times as large as my measure of the star. The coma is very dense near the nucleus; but loses itself pretty abruptly on the outside, though a gradual diminution is still very perceptible." These observations seem to corroborate the idea that Ceres is encompassed with an atmosphere of great density and elevation.

The Planet Pallas.—This planet revolves about the sun at the mean distance of two hundred and sixty-three millions of miles, and finishes its revolution in 1681 days, 17 hours, or in four years and seven and one-third months, which is within a day of the time of the revolution of Ceres. Its distance is likewise nearly the same as that planet, and the circumference of its orbit will also be nearly the same. This planet, however, is distinguished in a remarkable degree both from Ceres and from all the other planets by the very great inclination of its orbit to the plane of the ecliptic. This inclination is no less than thirty-four degrees, thirty-seven minutes, or nearly five times the inclination of Mercury's orbit, which was formerly reckoned to have the greatest inclination of any of the planetary orbits. The *eccentricity* of the orbit of Pallas is likewise greater than that of any of the other planets, being no less than 64,516,000 miles, so that this planet is 129,000,000 of miles nearer the sun in one part of its orbit than it is at the opposite extremity. Its greatest distance from the sun is 327,437,000 miles, and its least distance only 198,404,000 miles. Of course, its rate of motion in its orbit must be very variable, sometimes moving several thousands of miles an hour swifter at one time than at another, which is likewise the case, in a remarkable degree, with the planet Juno. Its *mean motion* is about 41,000 miles an hour.

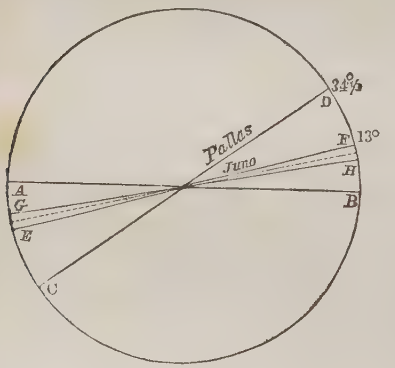
This planet presents a ruddy aspect, but less so than that of Ceres. It is likewise surrounded with a nebulosity somewhat like that of Ceres, but of less extent. The following are some of the observations of this planet by Schroeter and Herschel. The atmosphere of Pallas, according to Schroeter, is to that of Ceres as one hundred and one to one hundred and forty-six, or nearly as two to three. It undergoes similar changes, but the light of the planet exhibits greater variations. On the 1st of April, the atmosphere of Pallas suddenly cleared up, and the solid nucleus or disc of the planet was alone visible. About twenty-four hours afterward, the planet appeared pale and surrounded with fog, and this appearance continued during the 3d and 4th of April; but this phenomenon was not considered as arising from the diurnal rotation of the planet. The following are Herschel's observations: "April 22. In viewing Pallas, I cannot, with the utmost attention and under favorable circumstances, perceive any sharp termination which might denote a disc; it is rather what I would call a nucleus April 22 The appearance of Pallas is cometary; the disc, if it has any, being ill-defined. When I see it to the best advantage, it appears like a much-compressed, extremely small, but ill-defined planetary nebula. May 1. With a twenty feet reflector, power 477, I see Pallas well, and perceive a very small disc, with a coma of some extent about it, the whole diameter of which may amount to six or seven times that of the disc alone."—*Philosophical Transactions* for 1802.

The diameter of this planet has not, perhaps, been ascertained with sufficient precision. The difference in the estimates formed by Sir W. Herschel and M. Schroeter is very great. According to Schroeter, the diameter of Pallas is 2099 miles. If this estimate be nearly correct, Pallas will be about the size of our moon, and will comprehend on its surface nearly fourteen millions of square miles, which would accommodate a population of nearly four thousand millions, or five times the population of our world. The apparent mean diameter of this planet, comprehending its atmosphere, at its mean distance from the earth, according to Schroeter, is six and a half seconds.

Such is a brief view of the principal facts which have been ascertained respecting the planets Vesta, Juno, Ceres, and Pallas. All these bodies are situated between the orbits of Mars and Jupiter, and they are all invisible to the naked eye, except, perhaps, the planet Vesta, when in certain favorable positions. The real magnitudes of these planets are not to be considered as yet accurately determined; they may be a little greater or less than what is stated above, though it is not probable they are much larger. It may not be improper to remark, that on this point there is a great difference in the estimates of Schroeter and Herschel, the two principal observers who have investigated the phenomena of these planets, owing to the mode in which they measured the apparent diameters of these bodies. According to Sir W. Herschel, there is none of these bodies that exceeds 163 miles in diameter. But it is obvious, from the considerations I have stated in the description of Vesta, that bodies of such a small size could not be visible at such a distance, unless they were either luminous or composed of matter fitted to reflect the solar light with an extraordinary degree of brilliancy; and, therefore, it is far more probable that the estimates of Schroeter are nearest the truth.

Peculiarities of the New Planets.—These bodies present to our view various singularities and anomalies, which, at first sight, appear incompatible with the proportion and harmony which we might suppose originally to have characterized the arrangements of the solar system. In the first place, *their orbits have a much greater degree of inclination to the ecliptic than those of the old planets.* The orbit of Venus is inclined to the ecliptic in an angle of three degrees, twenty minutes; of Mars, one degree, fifty-one minutes; of Jupiter, one degree, eighteen minutes; of Saturn, two degrees and a half; and of Uranus, only forty-six minutes. But the inclination of the orbit of Vesta is seven degrees, nine minutes; of Juno, thirteen degrees; of Ceres, ten degrees, thirty-seven minutes; and of Pallas, no less than thirty-four degrees and a half, which is nineteen times greater than the inclination of Mars, and twenty-seven times greater than that of Jupiter. The proportion of these inclinations is represented in the following figure.

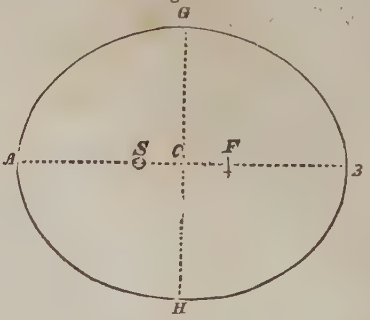
Fig. 46.



Let *A B* represent the plane of the ecliptic, and the line *C D* will represent the inclination of the orbit of Pallas = 34½ degrees, *E F*, the inclination of the orbit of Juno = 13 degrees; *G H*, the inclination of Vesta's = 7 degrees; and the dotted line the inclination of Ceres = 10½ degrees. All the older planets have their orbits much less inclined to the ecliptic, except Mercury, which has nearly the same inclination as Vesta; so that the zodiac would now require to be extended nearly five times its former breadth in order to include the orbits of all the planets.

2. *The orbits of these planets are in general more eccentric than those of the other planets;* that is, they move in longer and narrower ellipses. The following figure nearly represents the orbit of Pallas, and the orbit of Juno is nearly similar. *S* represents the sun in one of the foci of the ellipse; *C*, the center; *F*, the upper focus of the ellipse; and the whole line *A B*, the transverse diameter Now the distance *S C*, from the sun to the center, is the *eccentricity* of the orbit. This eccentricity in the case of Pallas, amounts to more than sixty-four and a half millions of miles. Consequently, when the planet is at *B*, which is called its *Aphelion*, or greatest distance from the sun, it is double its eccentricity, or the whole length of the line *S F* farther from the sun than when it is at the point *A*, which is called its *Perihelion*, or least distance from the sun, that is, it is 129 millions of miles farther from the sun in the one case than in the other, which is nearly *one-fourth* of the whole transverse diameter of the orbit *A B*. Consequently, its motion will be much slower, by several hundreds of thousands of miles a day, when near the point *B*, its aphelion, than when near its perihelion at the point *A;* and to a spectator on its surface the sun will appear more than double the size from the point *A* that he does from the point *B;* and its inhabitants (if any) will experience a greater difference in the intensity of the solar light which falls upon them in different periods of its year, than there is between Venus and the earth, or between the earth and Mars. On the other hand, the eccentricity of the orbits of the older planets is comparatively small. The eccentricity of the orbit of Venus is less than half a million of miles, which is only the 1-274th part of the transverse diameter of its orbit. The Earth's eccentricity is 1,618,000, or the 1-119th part; Jupiter's, 1-43d part; Saturn's, 1-38th part; and that of Uranus, about 1-43d part; whereas, the eccentricities of Pallas and Juno amount to nearly *one-eighth* part of the transverse axes of their orbits. Were the orbits of the old planets represented by figures ten times larger than the above diagram, they could not be distinguished from circles. In the above figure, the dotted line *G H* is the *conjugate* or shorter diameter of the ellipse. When the planet is at the points *G* and *H*, it is said to be at its *mean distance* from the sun, or at the middle point between its greatest and its least distance.

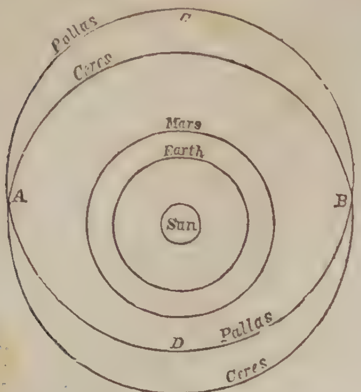
Fig. 47.



3. *The Orbits of several of the New Planets cross each other.*—This is a very singular and unaccountable circumstance in regard to the planetary orbits. It had been long observed that comets, in traversing the heavens in every direction, crossed the orbits of the planets; but, before the discovery of Pallas, no such anomaly was found throughout the system of the planets. For the orbits of all the other planets approach so nearly to circles, and are separated from each other by so many millions of miles, that there is no possibility of such intersection taking place. The following diagram represents the intersection of the orbits of Ceres and Pallas.

The central circle represents the sun; the two next circles the orbits of the earth and Mars; and the two outer circles, crossing each other, those

Fig. 48.



of Ceres and Pallas. In consequence of this intersection of their orbits, there is a *possibility*, especially if the periods of their revolutions were somewhat more different from each other, that the two planets might happen to strike against each other were they to meet at the points *A* and *B*, where the orbits intersect; a very singular contingence in the planetary system. It is owing to the very great eccentricity of the orbit of Pallas that it crosses the orbit of Ceres. It is several millions of miles nearer the sun in its perihelion (or at *A*, Fig. 47) than Ceres, when in the same point of its orbit. But when Pallas is in its aphelion (or at *B*, Fig. 47), its distance from the sun is several millions of miles greater than that of Ceres in the same point of its orbit. Suppose its aphelion at *C*, Fig. 48; it is farther from the sun than Ceres, and nearer at *D* its perihelion. The same things happen in the case of the other two planets, particularly Vesta. Juno is farther from the sun at its aphelion than Ceres in the same point of its orbit, and Vesta is farther from the sun in its aphelion than either Juno, Ceres, or Pallas, in their perihelions. The perihelion distance of Vesta is greater than that of Juno or Pallas. Hence it follows that Vesta may sometimes be at a greater distance from the sun than either Juno, Ceres, or Pallas, although its mean distance is less than that of either of them by twenty-eight millions of miles; so that *the orbit of Vesta crosses the orbits of all the other three*, and, therefore, it is a possible circumstance that a collision might take place between Vesta and any of these three planets, were they ever to meet at the intersection of their orbits. Were such an event to happen, it is easy to foresee the catastrophe that would take place. If the collision of two large ships, sailing at the rate of ten miles an hour, be so dreadful as to shatter their whole frame and sink them in the deep, what a tremendous shock would be encountered by the impulse of a ponderous globe, moving at the rate of forty thousand miles an hour? A universal disruption of their parts and a derangement of their whole constitution would immediately ensue; their axes of rotation would be changed; their courses in their orbits altered; fragments of their substance tossed about through the surrounding void, and the heavens above would appear to run into confusion. Though we cannot affirm that such an event is impossible or will never happen, yet we are sure it can never take place without the permission and appointment of Him who at first set these bodies in motion, and who superintends both the greatest and the most minute movements of the universe.

4. Another peculiarity in respect to these planets is, that *they revolve nearly at the same mean distances from the sun*. The mean distance of Juno is 254 millions of miles; that of Ceres, 262,903,000; and that of Pallas, 262,901,000, which is almost the same as Ceres. This is a very different arrangement from that of the other planets, whose mean distances are immensely different from each other; Mars being 50 millions of miles from the orbit of the earth, and 80 millions from the orbits of any of the new planets; Jupiter, 270 millions from Pallas; Saturn, 412 millions from Jupiter; and Uranus, 900 millions from Saturn. Except in the case of the new planets, the planetary system appears constructed on the most ample and magnificent scale, corresponding to the unlimited range of infinite space of which it forms a part.

5. These new planetary bodies *perform their revolutions in nearly the same periods*. The period of Vesta is 3 years, 7½ months; that of Juno, 4 years, 4⅓ months; of Ceres, 4 years, 7⅓ months; and of Pallas, 4 years, 7⅓ months. So that there are only three months of difference between the periods of Juno and Ceres, and scarcely the difference of a single day between those of Ceres and Pallas; whereas, the periods of the other planets differ as greatly as their distances. The period of Mercury is about 3 months; of Venus, 7½ months; of Mars, nearly 2 years; of Jupiter, 12 years; of Saturn, 29½; and of Uranus, nearly 84 years. A planet moving round the sun in almost the same period and at the same distance as another, is a singular anomaly in the solar system, and could scarcely have been surmised by former astronomers.

6. Another singularity is, that these bodies *are all much smaller than the other planets.* Mercury was long considered as the smallest primary planet in the system, but it is nearly four times larger in surface than Ceres, and contains eight times the number of solid miles. Mars, the next smallest planet, is seventeen times larger than Ceres; and Jupiter, the largest of the planets, is 170,000 times larger than Ceres, when their cubical contents are compared. The planets Vesta and Juno are smaller than Ceres, and Pallas is only a small degree larger. It is probable that all these four bodies are less in size than the secondary planets, or the satellites of Jupiter, Saturn, and Uranus.

Conclusions respecting the Nature of the New Planets.—The anomalies and peculiarities of these bodies, so very different from the order and arrangement of the older planets, open a wide field for reflection and speculation. Having been accustomed to survey the planetary system as a scene of proportion, harmony, and order, we can scarcely admit that these bodies move in the same paths, and are arranged in the same order as when the system was originally constructed by its Omnipotent Contriver. As we know that changes have taken place in our sublunary region since our globe first came from the hands of its Creator, so it is not contrary either to reason or observation to suppose that changes and revolutions, even on an ample scale, may take place among the celestial orbs. We have no reason to believe in the "incorruptibility" of the heavenly orbs, as the ancients imagined, for the planets are demonstrated to be *opaque* globes as well as the earth; they are diversified with mountains and vales, and, in all probability, the materials which compose their surfaces and interior are not very different from the substances which constitute the component parts of the earth. I have already alluded to the opinion of Dr. Olbers, that the new planets are only the fragments of a larger planet which had been burst asunder by some immense irruptive force proceeding from its interior parts. However strange this opinion may at first sight appear, it ought not to be considered as either very improbable or extravagant. We all profess to admit, on the authority of Revelation, that the earth was arranged in perfect order and beauty at its first creation; and on the same authority we believe that its exterior crust was disrupted, that "the cataracts of heaven were opened, and the fountains of the great deep broken up," and that a flood of waters ensued which covered the tops of the loftiest mountains, which transformed the earth into one boundless ocean, and buried the immense myriads of its population in a watery grave. This was a catastrophe as tremendous and astonishing as the bursting asunder of a large planet. Although physical agents may have been employed in either case to produce the effect, yet we must admit, in consistency with the Divine perfections, that no such events could take place without the direction and control of the Almighty, and that, when they do happen, whatever appalling or disastrous effects they may produce, they are in perfect consistency with the moral laws by which his universal government is directed.

We know that a moral revolution has taken place among the human race since man was created, and that this revolution is connected with most of the physical changes that have happened in the constitution of our globe; and, if we believe the sacred historian, we must admit that the most prominent of these physical changes or concussions was the consequence or punishment of man's alienation from God and violation of his laws. As the principles of the Divine government must be essentially the same throughout every part of the boundless empire of the Almighty, what should hinder us from concluding that a moral cause, similar to that which led to the physical convulsions of our globe, may have operated in the regions to which we allude, to induce the Governor of the universe to undermine the constitution, and to dash in pieces the fabric of that world? The difference is not great between bursting a planet into a number of fragments and cleaving the solid crust of the earth asunder, removing rocks and mountains out of their place, and raising the bed of the ocean from the lowest abyss, so as to form a portion of elevated land; all which changes appear to have been effected in the by-past revolutions of our globe, and both events are equally within the power and the control of Him "who rules in the armies of heaven, and among the inhabitants of the earth," whatever physical agents he may choose to select for the accomplishment of his purposes. In the course of the astronomical discoveries of the two preceding centuries, views of the universe have been laid open which have tended to enlarge our conceptions of the attributes of the Deity, and of the magnificence of that universe over which he presides: and who knows but that the discovery of those new planets described above, and the singular circumstances in which they are found, are intended to open to our view a new scene of the physical operations of the Creator, and a new display of the operations of his moral government? For all the manifestations of God in his works are doubtless intended to produce on the mind not only an intellectual, but also a *moral* effect; and in this view the heavens ought to be contemplated with as much reverence as the revelations of his word. As the great Sovereign of the universe is described by the inspired writers as being the "King Eternal and *Invisible*," so we can trace his perfections and the character of his moral government only, or chiefly, through the medium of those displays he gives of himself in his wonderful operations both in heaven and on earth. And since in the course of his providence, he has crowned with success the inventive genius of man, and led him on to make the most noble discoveries in reference to the amplitude and grandeur of his works, we have every reason to conclude that such inventions and such discoveries, both in the minute parts of creation and in the boundless sphere of the heavens, are intended to carry forward the human mind to more expansive views of his infinite attributes, of the magnificence of his empire, and of the *moral economy* of the government which he has established throughout the universe.

The hypothesis of the bursting of a large planet between Mars and Jupiter accounts in a great measure, if not entirely, for the anomalies and apparent irregularities which have been observed in the system of the new planets; and if this supposition be not admitted, we cannot account, on any principle yet discovered, for the singular phenomena which these planets exhibit. Sir David Brewster, who has entered into some particular discussions on this subject, after stating the remarkable coincidences between this hypothesis and actual observation, concludes in the following words: "These singular resemblances in the motions of the greater fragments and in those of the lesser fragments, and the striking coincidence between theory and observation in the eccentricity of their orbits, in their inclination to the ecliptic, in the position of their nodes, and in the places of their aphelia, are phenomena which could not possibly result from chance, and which concur to prove, with an evidence amounting almost to demonstration, that the four new planets have diverged from one common node, and have therefore composed a single planet."

Another species of phenomena, on which a great mystery still hangs, might be partly elucidated were the above hypothesis admitted, and that is the singular but not well-attested fact of large masses of solid matter falling from the higher regions of the atmosphere, or what are termed *meteoric stones*. Few things have puzzled philosophers more than to account for large fragments of compact rocks proceeding from regions beyond the clouds, and falling to the earth with great velocity. These stones sometimes fall during a cloudy, and sometimes during a clear and serene atmosphere; they are sometimes accompanied with explosions, and sometimes not. The following statements, selected from respectable authorities, will convey some idea of the phenomena peculiar to these bodies. The first description I shall select is given by J. L. Lyons, Esq., F. R. S., and contained in the "Transactions of the Royal Society." It is entitled, "Account of the Explosion of a Meteor, near Benares, in the East Indies, and of the falling of some Stones at the same time." The following are only the leading particulars. "A circumstance of so extraordinary a nature as the fall of stones from the heavens could not fail to excite the wonder and to attract the attention of every inquisitive mind. On the 19th of December, 1798, about eight o'clock in the evening, a very luminous meteor was observed in the heavens by the inhabitants of Benares and the parts adjacent, in the form of a large ball of fire; it was accompanied by a loud noise resembling thunder, and a number of stones fell from it about fourteen miles from the city of Benares. It was observed by several Europeans, as well as natives, in different parts of the country. It was likewise very distinctly observed by several European gentlemen and ladies, who described it as a large ball of fire, accompanied with a loud rumbling noise not unlike an ill-discharged platoon of musketry. It was also seen and the noise heard by several persons at Benares. When a messenger was sent next day to the village near which they had fallen, he was told that the natives had either broken the stones to pieces, or given them to the native collector or others. Being directed to the spot where they fell, he found four, most of which the fall had buried six inches deep in the earth.—He learned from the inhabitants that, about eight o'clock in the evening, when retired to their habitations, they observed a very bright light, proceeding as from the sky, accompanied with a loud clap of thunder, which was immediately followed by the noise of heavy bodies falling in the vicinity. They did not venture out to make any inquiries until next morning, when the first circumstance that attracted their attention was the appearance of the earth being turned up in several parts of their fields, where, on examination, they found the stones. Several other stones of the same description were afterward found by different persons. One of these stones, of about two pounds' weight, fell through the top of the watchman's hut, close to which he was standing, and buried itself several inches in the floor, which was of consolidated earth. The form of the more perfect stones appeared to be that of an irregular cube, rounded off at the edges, but the angles were to be observed on most of them. At the time when the meteor appeared the sky was perfectly serene; not the smallest vestige of a cloud had been seen since the 11th of the month, nor were any observed for many days after. It is well known there are no volcanoes on the continent of India, and therefore they could not derive their origin from any such source; and no stones have been met with in the earth, in that part of the world, which bear the smallest resemblance to those now described."

On the 13th of December, 1795, a stone weighing fifty-six pounds fell near Wold cottage, in Yorkshire, at three o'clock, P. M. It penetrated through twelve inches of soil and six inches of solid chalk rock, and, in burying itself, had thrown up an immense quantity of earth to a great distance; as it fell, a number of explosions were heard as loud as pistols. In the adjacent villages the sound was heard as of great guns at sea; but at two adjoining villages the sounds were so distinct of something passing through the air to the residence of Mr. Topham, that five or six people came up to see if anything extraordinary had happened at his house. When the stone was extracted, it was warm, smoked, and smelt very strong of sulphur. The day was mild and hazy, but there was no thunder nor lightning the whole day. No such stone is known in the country, and there is no volcano nearer than Vesuvius or Hecla. The constituent parts of this stone were found exactly the same as those of the stones from Benares.*

On the 26th of April, 1803, an extraordinary shower of stones happened at L'Aigle, in Normandy. About one o'clock, the sky being almost serene, a rolling noise like that of thunder was heard, and a fiery globe of uncommon splendor was seen, which moved through the atmosphere with great rapidity. Some moments after there was heard at L'Aigle, and for thirty leagues around in every direction, a violent explosion, which lasted five or six minutes; after which was heard a dreadful rumbling like the beating of a drum. In the whole district there was heard a hissing noise like that of a stone discharged from a sling, and a great many mineral masses, exactly similar to those distinguished by the name of *meteor stones*, were seen to fall. The largest of these stones weighed seventeen pounds and a half. The Vicar of St. Michael's observed one of the stones fall with a hissing noise at the feet of his niece in the courtyard of his parsonage, and that it rebounded more than a foot from the pavement.—When it was taken up and examined, it was found to resemble the others in every respect. As a wire manufacturer was working with his men in the open air, a stone grazed his arm and fell at his feet, but it was so hot that, on attempting to take it up, he instantly let it fall again. The celebrated Biot was deputed by government to repair to the spot and collect all the authentic facts in relation to this phenomenon, an account of which was afterward published in a long memoir. He found that almost all the residents of twenty hamlets declared that they were eyewitnesses of the shower of stones which was darted from the meteor.—The interior parts of these stones resembled those of all the meteorites analyzed by Messrs. Howard and Vauquelin, such as those described above. They all contain silica, magnesia, oxyd of iron, nickel, and sulphur, in various proportions.—Their specific gravity is about three and one-third or three and one-half times heavier than water.

The following are a few brief statements in relation to this subject. In 1492, November 7, a stone of 260 lbs. fell at Ensisheim, in Alsace. It is now in the library of Colmar, and has been reduced to 150 lbs., in consequence of the abstraction of fragments. The famous Gassendi relates that a stone of a black metallic color fell on Mount Vaision, in Provence, November 29, 1637. It weighed 54 lbs., and had the size and shape of the human head. Its specific gravity was three and one-half times that of water. 1654, March 30: A small stone fell at Milan and killed a Franciscan 1706, June 7: A stone of 72 lbs. fell at Larissa, in Macedonia; it smelled of sulphur, and was like the scum of iron. 1751, May 26: Two masses of iron, of 71 lbs. and 16 lbs., fell in the district of Agram, the capital of Croatia. The largest of these is now in Vienna. 1790, July 24: A great shower of stones fell at Barbotan, near Roquefort, in the vicinity of Bourdeaux. A mass fifteen inches in diameter, penetrated a hut and killed a herdsman and a bullock. Some of the stones weighed 25 lbs., and others 30 lbs. July, 1810: A large ball of fire fell from the clouds at Shahabad, which burned five villages, destroyed the crops, and killed several men and women. November 23, 1810: Three stones fell in the commune of Charionville and neighborhood of Orleans. These stones were precipitated perpendicularly, and without the appearance of any light or ball of fire. One of them weighed 20 lbs., and made a hole in the ground in a perpendicular direction, driving up the earth to the hight of eight or ten feet. It was taken out half an hour after, when it was still so hot that it could scarcely be held in the hand. The second formed a hole three feet deep, and weighed 40 lbs. 1812, April 15: A stone, the size of a child's head, fell at Erxleben, and a specimen of it is in the possession of Professor Haussmann, of Brunswick. 1814, September 1: A few minutes before midday, while the sky was perfectly serene, a violent detonation was heard in the department of the Lot and Garonne. This was followed by three or four others, and finally by a rolling noise, at first resembling a discharge of musketry, afterward the rumbling of carriages, and, lastly, that of a large building falling down. Stones were immediately after precipitated to the ground, some of which weighed 18 lbs., and sank into a compact soil to the depth of eight or nine inches, and one of them rebounded three or four feet from the ground.—1818, July 29, O. S.: A stone of 7 lbs. weight fell at the village of Slobodka, in Russia, and penetrated nearly sixteen inches into the ground. It had a brown crust with metallic spots. In 1825, February 10: A meteoric stone weighing 16 lbs. 7 oz., fell from the air at Nanjemoy, Maryland.—It was taken from the ground about half an hour after its fall, was sensibly warm, and had a sulphurous smell.

---

* See a long paper on this subject, by E. Howard, Esq., F. R. S. in "Transactions of the Royal Society of London" for 1802.

Several hundreds of instances similar to the above might be produced of large masses of stones having fallen from the upper regions upon the earth.* These stones, although they have not the smallest analogy with any of the mineral substances already known, either of a volcanic or any other nature, have a very peculiar and striking analogy with each other. They have been found at places very remote from each other, and at very distant periods. The mineralogists who have examined them agree that they have no resemblance to mineral substances, properly so called, nor have they been described by mineralogical authors. They have, in short, a peculiar aspect, and peculiar characters which belong to no native rocks or stones with which we are acquainted. They appear to have fallen from various points of the heavens, at all periods, in all seasons of the year, at all hours both of the day and night, in all countries in the world, on mountains and on plains, and in places the most remote from any volcano. The luminous meteor which generally precedes their fall is carried along in no fixed or invariable direction; and as their descent usually takes place in a calm and serene sky, and frequently in cloudless weather, their origin cannot be traced to the causes which operate in the production of rain, thunder-storms, or tornadoes.

From a consideration of these and many other circumstances, it appears highly probable, if not absolutely certain, that these substances proceed from regions far beyond the limits of our globe. That such solid substances, in large masses, could be generated in the higher regions of the atmosphere, is an opinion altogether untenable, and is now generally discarded, even by most of those philosophers who formerly gave it their support. That they have been projected from volcanoes is a hypothesis equally destitute of support; for the products of volcanoes are never found at any great distance from the scene of their formation, and the substances they throw out are altogether different in their aspect and composition from meteoric stones. Beside, these stones, in most instances, have descended to the earth in places removed hundreds, or even thousands of miles from any volcanic mountain, and at times when no remarkable eruption was known to take place. Perceiving no probability of their having their origin either in the earth or the atmosphere, Dr. Hutton, Poisson, La Place, and others, conjectured that they were projected from the moon. They demonstrated the abstract proposition, that a heavy body projected with a velocity of six thousand feet in a second, may be carried beyond the sphere of the moon's attraction, and come within the attraction of the earth. But it has never yet been proved that volcanoes exist on the surface of the moon; and, although they did exist, and were as large and powerful as terrestrial volcanoes, they would have no force sufficient to carry large masses of stone with such a rapid velocity over a space of several thousands of miles. Beside, were the moon the source of meteoric stones, ejected from the craters of volcanoes, we should expect such volcanic productions to exhibit several varieties of aspect and composition, and not the precise number of ingredients which are always found in meteoric stones.—From a consideration of the difficulties attending this hypothesis, La Place was afterward induced to change his opinion.

In order to trace the origin of meteoric stones, we are therefore under the necessity of directing our views to regions far beyond the orbit of the moon. On the supposition that the bursting of a large planet was the origin of the small planets Vesta, Juno, Ceres, and Pallas, we may trace a source whence meteoric stones probably originate. "When the cohesion of the planet was overcome by the action of the explosive force, a number of little fragments, detached along with the greater masses, would, on account of their smallness, be projected with very great velocity; and, being thrown beyond the attraction of the greater fragments, might fall toward the earth when Mars happened to be in the remote part of his orbit. When the portions which are thus detached arrive within the sphere of the earth's attraction, they may revolve round that body at different distances, and may fall upon its surface, in consequence of a diminution of their centrifugal force; or, being struck by the electric fluid, they may be precipitated upon the earth, and exhibit all those phenomena which usually accompany the descent of meteoric stones." This opinion appears to have been first broached by Sir David Brewster, and is stated and illustrated in the "Edinburgh Encyclopedia," article *Astronomy,* and in vol. ii, of his edition of "Ferguson's Astronomy." Though not unattended with difficulties, it is perhaps the most plausible hypothesis which has yet been formed to account for the extraordinary phenomena of heavy substances falling with velocity upon the earth through the higher regions of the atmosphere.

On this subject I would consider it as premature to hazard any decisive opinions. I have laid down the above facts before the reader that he may be enabled to exercise his own judgment and form his own conclusion. I have stated them particularly with this view, that they may afford a subject of investigation and reflection. For all the works and dispensations of the Almighty, both in the physical and moral world, are worthy of our contemplation and research, and may ultimately lead both to important discoveries and to moral instruction. Though "the ways of God" are, in many instances, "past finding out," yet it is our duty to investigate them so far as our knowledge and limited powers will permit For as we are told, on the highest authority, that "the works of the Lord are great and marvelous," so it is declared that "they will be sought out" or investigated "by all those who have pleasure therein." There is, perhaps, no fact throughout the universe, however minute in itself, or however distant from the scene we occupy, but is calculated, when properly considered, to convey to the mind an impression of the character of the Deity and of the principles of his moral government. The mere philosopher may content himself with the application of the principles of chemistry and mathematics to the phenomena of matter and motion; and it is highly proper and necessary that both chemical and mathematical analysis be applied for the investigation of the laws and order of the material universe; but the man who recognizes the principles of Divine Revelation will rise to still higher views. From nature he will ascend to nature's God, and trace the invisible perfections of the Eternal from the visible scene of his works; and, from his physical operations, will endeavor to learn something of the order and economy of his *moral* administration.

---

* For more particular details on this subject, the reader may consult "The Edinburgh Encyclopædia," art. *Meteorite.* The "Edin. Phil. Journal," No. 2, p. 221-255. "Phil. Magazine," vol. xiii. "Retrospect of Philosophical Discoveries," 1805, vol. 1, p. 201-210, &c., &c.

If there be any foundation for the hypothesis to which we have adverted, it might be a question and a subject of consideration at what period the disruption of the supposed planet may have taken place. If the history of the fall of meteoric stones would be considered as throwing any light on this question, it will follow that such an event must have taken place at a very distant period: for the descent of such stones can be traced back to periods more than a thousand years before the commencement of the Christian era; perhaps even to the days of Joshua, when a shower of stones destroyed the enemies of Israel,* which would lead us to conclude that more than three thousand years must have elapsed since such an event. It might likewise be a subject of inquiry, why the Deity has exposed the earth to the impulse of such ethereal agents; for the fall of meteoric stones is evidently attended with imminent danger to the inhabitants of those places on which they fall. The velocity and impetus with which they descend are sufficient to cause instant death to those whom they happen to strike, and even to demolish human habitations, as happened in several of the instances above recorded. Would the Deity have permitted a world peopled with innocent beings to be subjected to such accidents and dangers? If not, is it not a presumptive proof that man, in being exposed to such casualties from celestial agents, as well as from storms, earthquakes, and volcanoes, is not in that state of primeval innocence in which he was created? And if we suppose that a moral revolution was the cause of the catastrophe which happened to the planet to which we allude, we may trace both a physical and a moral connection, however distant, between the earth and that planet; for if the stones to which we allude are a part of the wreck of that world, they have been the means of exciting alarm among various tribes of the earth's population, and of producing destruction and devastation; so that one depraved world has been the instrument in some degree of punishing another.

But perhaps I have gone too far in such speculations. I have stated them with the view of showing that we might occasionally connect our moral views of the Deity with the contemplation of the material fabric of the universe. When, through the medium of our telescopes and our physical investigations, we obtain a glimpse of the order and economy of a distant region of the universe, it may be considered as a new manifestation of the Deity, and it is our duty to deduce from it those instructions it is calculated to convey. And although we may occasionally deduce erroneous conclusions from existing facts, yet such speculations and reflections may sometimes have a tendency to excite an interesting train of thought, and to inspire us with an ardent desire of beholding the scene of the universe and the plan of the Divine administration more completely unfolded, in that world where the physical and moral impediments which now obstruct our intellectual vision shall be forever removed

VI. ON THE PLANET JUPITER.

Next to Pallas, in the order of the system, is the planet Jupiter. This planet, when nearest the earth, is the most splendid of all the nocturnal orbs, except Venus and the moon. Its distance from the sun is 495,000,000 of miles, and the circumference of its orbit, 3,110,000,000 of miles. Around this orbit it moves in eleven years and three hundred and fifteen days, at the rate of nearly thirty thousand miles every hour. When nearest to the earth, at the time of its opposition to the sun, it is about 400,000,000 of miles distant from us. A faint idea of this distance may be acquired by considering that a cannon-ball, flying five hundred miles every hour, would require more than ninety-one years to pass over this space; and a steam-carriage, moving at the rate of twenty miles an hour, would require nearly two thousand three hundred years before it could reach the orbit of Jupiter. When at its greatest distance from the earth, about the time of its conjunction with the sun, this planet is distant from us no less than 590,000,000 of miles; yet its apparent size, in this case, does not appear very much diminished, although it is 190,000,000 of miles farther from us in the latter case than in the former. When viewed with a telescope, however, it appears sensibly larger and more splendid at the period of its opposition than when near the point of its conjunction.

Diurnal Rotation.—This planet has been found to revolve around its axis in the space of nine hours, fifty-five minutes, and forty-nine and a half seconds. This discovery was made by observing a small spot in one of the belts, which appeared gradually to move across the disc of the planet. Mr. Hook appears to have first observed it in the year 1664; and in the following year, 1665, Cassini, that accurate observer of the heavens, perceived the same spot, which appeared round, and moved with the greatest velocity when in the middle, but was narrower, and moved more slowly as it approached nearer the edge of the disc, which showed that the spot adhered to the body of Jupiter, and was carried round upon it. This spot continued visible during the following year, so that Cassini was enabled to determine the period of Jupiter's rotation to be nine hours and nearly fifty-six minutes. This rotation is far more rapid than that of any of the other planets, so far as we know, and nearly equals the velocity of Jupiter in his annual course round the sun. The circumference of this planet is 278,600 miles, and, therefore, its equatorial parts will move with a velocity of 28,000 miles an hour, which is

---

* These stones, in our translation of the Bible, are called *hailstones*, but without any reason, since the original word, *abenim*, signifies stones in general according to the definition given in Parkhurst's Hebrew Lexicon; and in the book of Job, chap. xxviii. 3, the word is translated *stones of darkness;* meaning, undoubtedly, metallic stones or metals which are searched out from the bowels of the earth.

3000 miles more than the equatorial parts of the earth's surface move in twenty-four hours. This rapid velocity of the tropical regions of Jupiter, and of the places which lie adjacent to them, will have the effect of rendering all bodies *lighter* than they would be were the motion of rotation as slow as that of the earth. The gravity of bodies at the surface of Jupiter is more than twice as great as at the surface of the earth, on account of his superior bulk; so that a body weighing one pound at the equatorial surface of the earth would weigh two pounds four ounces and a half at the surface of Jupiter. If, therefore, we were transported to the surface of that planet, we should be a burden to ourselves, being pressed down with more than double our present weight, and having but the same strength to support it. But Jupiter is *eleven* times larger in circumference than the earth; and hence, if both planets revolved on their axes in the same time, the centrifugal force on Jupiter would be eleven times greater than with us. But the squares of the number of revolutions performed in the same time by the earth and Jupiter; that is, the square of twenty-four hours, and the square of nine hours, fifty-six minutes, are nearly as one to six; therefore, a body placed on Jupiter will have sixty-six* times a greater centrifugal force than with us, which would sensibly relieve the weight of the inhabitants if they stood in need of it. This rapid rotation would of itself relieve them of one-eighth or one-ninth of their whole weight; or, in other words, a body weighing eight stone at the equator of Jupiter, if the planet stood still, would gravitate with a force of only seven stone on the commencement of its diurnal rotation, at the rate at which we now find it.

It may perhaps be surmised by some that, since the semidiameter of Jupiter is eleven times greater than that of the earth, the attraction or weight of bodies on its surface ought to be eleven times greater than on the surface of our globe. This would be the case if the matter in Jupiter were as dense as in the earth; and the weight of bodies would, of course, be in proportion to their semidiameter, or the distance of the surface from the centers of these bodies. But the density of Jupiter is only a little more than that of water, while the density of the earth is five times greater. If the density of Jupiter were as great as that of the earth, and, consequently, the weight of bodies on its surface eleven times greater, men of our stature and make could scarcely be supposed to support eleven times the weight of such bodies as ours, but behooved to be almost chained down to the surface of the planet by their own gravity; and were we to suppose them of a larger stature, this inconvenience would become the greater; for the least of any species of animated beings have generally the greatest nimbleness and agility of motion. This circumstance is perhaps one of the reasons why the larger planets of the system have the least degree of density: for if Jupiter were composed of materials as dense as those of Mercury, organized beings like man would be unable, without a supernatural power, to traverse the surface of such a planet.

In consequence of the rapid motion of Jupiter, the days and nights will be proportionably short. The sun will appear to move through the whole celestial hemisphere, from the eastern to the western horizon, in less than five hours, and all the planets and constellations will appear to move with the same rapidity: so that the apparent motions of all these bodies will be perceptible to the eye when contemplating them only for a few moments, excepting those which appear near the polar regions. The sky of this planet will, therefore, assume an air of sublimity superior to ours, in consequence of all the bodies it contains appearing to sweep so rapidly around, and to change their positions in so short a space of time. As Jupiter moves round the sun in 4332½ of our days, and round its axis in nine hours, fifty-six minutes, there will be 10,470 days in the year of that planet.

Magnitude and Superficial Contents of the Globe of Jupiter.—This planet is the largest in the system, being 89,000 miles in diameter, and, consequently, *fourteen hundred times* larger than the earth. Its surface contains 24,884,000,000, or twenty-four thousand eight hundred and eighty-four millions of square miles, which, at the rate of population formerly stated, 280 inhabitants to a square mile, would be sufficient for the accommodation of 6,967,520,000,000, or nearly *seven billions* of inhabitants, which is more than *eight thousand seven hundred times* the present population of our globe, and nearly *fifty* times the number of human beings that have existed on the earth since its creation. Although the one-half of this planet were covered with water, which does not appear to be the case, it would still be ample enough to contain a population more than four thousand times larger than that of our globe. If such a population actually exist, as we have little reason to doubt, it may hold a rank, under the Divine government, equal to several thousands of worlds such as ours. Such an immense globe, replenished with such a number of intellectual beings, revolving with such amazing rapidity round its axis, moving forward in its annual course 30,000 miles every hour, and carrying along with it four moons larger than ours to adorn its firmament, presents to the imagination an idea at once wonderful and sublime, and displays a scene of wisdom and omnipotence worthy of the infinite perfections of its Creator.

Discoveries which have been made in relation to Jupiter by the Telescope.—Jupiter presents a splendid and interesting appearance when viewed with a powerful telescope. His surface appears much larger than the full moon to the naked eye; his disc is diversified with darkish stripes; his satellites appear sometimes in one position and sometimes in another, but generally in a straight line with each other. Sometimes two of them are seen on one side of the planet and two on another; sometimes two only are visible, while the other two are eclipsed either by the disc or the shadow of Jupiter; and sometimes all the four may be seen on one side and in a straight line from the planet, in the order of their distances; so that these moons present a different aspect and relation to each other every successive evening.

These moons were first seen by Galileo, in the year 1610, by means of a telescope he had constructed, composed of two glasses, a concave next the eye, and a convex next the object, which magnified about thirty-three times. No further discoveries were made in relation to this planet until about the year 1633, when the *belts* were discovered by Fontana Rheita, Riccioli, and several others. They were afterward more particularly observed and delineated by Cassini. These belts appear like dark stripes across the disc of the planet, and are generally parallel to one another and to the planet's equator. They are somewhat variable, however, both as to their number and their distance from each other, and sometimes as to their position On certain occasions *eight* have been seen at a time; at other times only one. Though they are generally parallel to one another, yet a piece of a belt has been seen in an oblique position to the rest, as in Fig. 49. They also vary in breadth; for one belt has been observed to have grown a good deal narrower than it was, when a neighboring belt has been increased in breadth, as if the one, like a fluid, had flowed into the other. In favor of this opinion, it is stated in the "Memoirs of the Royal Academy of Sciences," that a part of an oblique belt was observed to lie so as to form a communication between them, as represented in Fig. 49. At one time, says Dr. Long, the belts have continued without sensible variations for nearly three months; at another time a new belt has been formed in an hour or two. They have sometimes been seen broken up and distributed over the whole face of the planet, in which state they are exhibited in some of the delineations of Sir W. Herschel; but this phenomenon is extremely rare, and does not appear to have been noticed by any other observer. In the year 1787, Schroeter saw two dark belts in the middle of Jupiter's disc: and near to them two white and luminous belts, resembling those which were seen by Campani in 1664. The equatorial zone which was comprehended between the two dark belts had assumed a dark gray color, bordering upon yellow. The northern dark belt then received a sudden increase of size, while the southern one became partly extinguished, and afterward increased into an uninterrupted belt. The luminous belts also suffered several changes, growing sometimes narrower, and sometimes one-half larger than their original size.

---

* That is, 11×6=66.

The following figures represent some of the appearances of the belts of Jupiter.

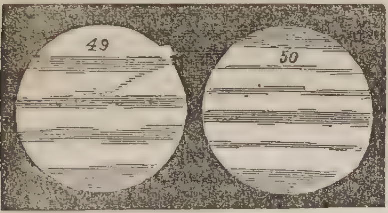


Fig. 49, represents a view of Jupiter's belts by Cassini. Fig. 50, a view from Dr. Hook, as delineated in the "Philosophical Transactions" for 1666, which was taken by a sixty feet refracting telescope. The small black spot on the middle belt, which did not appear at the beginning of the observation, and which moved about a third or fourth part across the disc in the space of ten minutes, was judged to be the shadow of one of the satellites moving across the disc of the planet. Fig 51, exhibits a view of Jupiter as he appeared about the end of 1832 and the beginning of 1833, which was taken by means of an achromatic telescope, with magnifying powers of 150 and 180 times. Fig. 52, is a view taken with the same telescope in 1837. In this view the principal belt near the planet's equator appeared dark, distinct, and well-defined; but the other two belts at either pole were extremely faint, and could only be perceived after a minute inspection. Fig. 53, is a view in which a bright and a dark spot were perceived on one of the belts; and Fig. 54, a view by Sir John Herschel. I have had an opportunity of viewing Jupiter with good telescopes, both reflecting and achromatic, for twenty or thirty years past; and, among several hundreds of observations, I have never seen above four or five belts at one time.—The most common appearance I have observed is that of two belts, distinctly marked, one on each side of the planet's equator, and one at each pole, generally broader, but much fainter than the others. I have never perceived much change in the form or position of the belts during the same season, but in successive years a slight degree of change has been perceptible, some of the belts having either disappeared, or turned much fainter than they were before, or shifted somewhat their relative positions; but I have never seen Jupiter without at least two or three belts. Some of the largest of these belts, being at least the one-eighth part of the diameter of the planet in breadth, must occupy a space at least 11,000 miles broad and 278,000 miles in circumference; for they run along the whole circumference of the planet, and appear of the same shape during every period of its rotation. It is probable that the smallest belts we can distinctly perceive by our telescopes are not much less than a thousand miles in breadth.

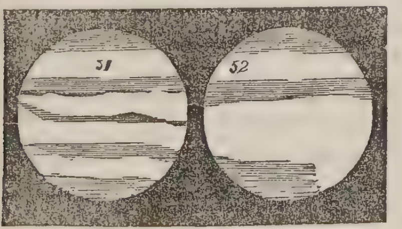
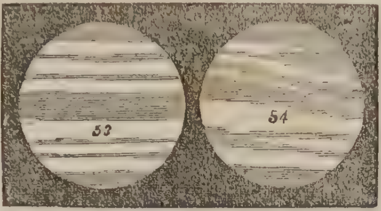




What these belts really are has been a subject of speculation and conjecture among astronomers, but it is difficult to arrive at any definite conclusion. By some they have been regarded as immense strata of clouds in the atmosphere of Jupiter; while others imagine that they are the marks of great physical changes which are continually agitating the surface of this planet. I am inclined to think that the dark belts are portions of the real surface of the planet, and that the brighter parts are something analogous to clouds, or other substances with which we are unacquainted, floating in its atmosphere, at a considerable elevation above its surface. That the dark belts are the body of the planet appears highly probable from this consideration, that the spot by which the rotation of Jupiter was determined has been always found in connection with one of the dark belts; and as this spot must be considered as a permanent one on the body of Jupiter, so the belt with which it is connected must be considered as a portion of the real body of the planet. It is absurd and preposterous to suppose, as some have done, that the changes on the surface of Jupiter are produced by physical convulsions, occasioned by earthquakes and inundations; for, in such a case, the globe of Jupiter would be unfit for being the peaceful abode of rational inhabitants. What should we think of a world where 5000 miles of ocean occasionally inundated a corresponding portion of the land, or where earthquakes sometimes swallowed up continents of several thousands of miles in length and breadth? Such physical catastrophes recurring every year on such a splendid and magnificent globe as Jupiter would not only render it unfit for the habitation of any beings, but would imply a reflection on the wisdom and benevolence of the great Creator. Whatever opinions, therefore, we may adopt, respecting the phenomena of this planet, they ought to be such as are consistent with the idea of a habitable world and with the perfections of the Deity. Were the belts of Jupiter permanent and invariable, it would be comparatively easy to account for the phenomena which appear on his surface; for the dark belts might be considered as seas, and the brighter portions of his surface as land. But as these belts, whether bright or dark, are found to be variable, we must have recourse to another hypothesis for their explanation, or be content, in the meantime, to confess our ignorance. Our opinions and conjectures respecting the circumstances of other worlds are too frequently guided merely by what we know of the objects and operations which exist on our globe; and we are apt to think that the arrangements of other globes destined for the abode of intellectual beings must be similar to those of our own. We talk of physical convulsions, earthquakes, and inundations in Jupiter, and of volcanic eruptions in the sun and moon, as if these phenomena were as common in other worlds as in the earth; whereas it is not improbable that they are *peculiar* to our globe, and that they are connected with the moral, or rather *demoralized* state of its present inhabitants. There is an *infinite variety* in the system of nature; and it is highly probable that there is no world in the universe that exactly resembles another. Although Jupiter moves round the sun, and turns upon his axis by the same laws which direct the motions of our globe, yet there may be as great a difference in the arrangements connected with this planet and those of the earth, as there is between the constitution of the earth and that of a planet which revolves around the star Sirius.—Would it be altogether improbable to suppose that the globe of Jupiter is partly inclosed within a sphere of semitransparent substance, at a considerable elevation above his surface, or rather within parallel rings, like an Armillary sphere composed of such a substance, which vary their position, and sometimes surround one part of his globe and sometimes another? These rings, of whatever substance they might be composed, might serve to reflect the rays of the sun so as to produce an addition of light and heat, and, at the same time, by exhibiting a variety of colors and motions, to diversify and adorn the firmament of this planet. Almost any supposition is preferable to the idea of a continued scene of physical convulsions.—The idea now thrown out is not more extravagant than that of a planet nearly as large as Jupiter being surrounded with two concentric rings. Had we not discovered the rings of Saturn, we should never have formed the idea of a world environed with such an appendage. As a corroboration of the idea that the bright stripes which appear on this planet surround its body at a considerable elevation, it has been observed by Sir John Herschel, "that the dark belts do not come up in all their strength to the edge of the disc, but fade away gradually before they reach it;" an almost decisive proof that the bright belts inclose the dark ones, or, in other words, the body of the planet; and that they are elevated above the dark globe of Jupiter, in all probability, not less than a thousand miles.

Whatever opinion we may form as to the constitution of this planet, the phenomena it presents afford a vast field for investigation and reflection. If it be a fact, as has been asserted by credible observers, that two belts have gradually disappeared during the time of an observation, and that, at another time, a new belt has been formed in an hour or two, agents far more powerful than any with which we are acquainted must have been in operation to produce such an effect, and changes more extensive than any which take place in our terrestrial sphere must have happened in the regions connected with Jupiter; for some of the belts of this planet are from five to ten thousand miles in breadth; and if those alluded to extended quite across the disc of the planet, they must have been more than one hundred and thirty thousand miles in length. Yet such a change may have taken place, not only without convulsions, causing terror and confusion, but to the admiration and joy of the inhabitants of that globe, as opening up a new and striking scene in the canopy of heaven; for if we suppose such bright belts or circles as we have imagined rapidly to shift their position in the canopy above, such a grand effect might in a short time be produced.

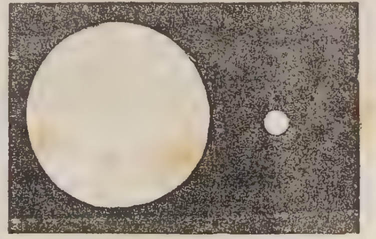
Beside the belts, spots of different kinds, some of them brighter and some darker than the belts, have been occasionally seen. The spot by which Jupiter's rotation was determined is the largest and of the longest continuance of any hitherto observed. Its diameter is one-tenth of the diameter of Jupiter, and it is situated in the northern part of the southern belt. Its center, when nearest that of the planet, is distant from the center of Jupiter about one-third of the semidiameter of the planet. This spot was first perceived by Hook and Cassini in the years 1664, 1665, and 1666. It appeared and vanished eight times between the years 1665 and 1708. From 1708 until 1713 it was invisible; the longest time of its continuing visible was three years, and the longest period of its disappearing was from 1708 to 1713. It has evidently some connection with the southern belts; for it has never been seen when that disappeared, though that belt has often been visible without the spot. Beside this ancient spot, as it is called, Cassini, in the year 1699, saw one of less stability, which did not continue of the same shape and dimensions, but broke into several small ones, of which the revolution was but 9 hours, 51 minutes; and two other spots which revolved in 9 hours, 52½ minutes. The large spot described above, being about the one-tenth of the diameter of Jupiter, must have been more than 8000 miles in extent, and, consequently, larger than the diameter of the earth. When Cassini had assured himself of the period of rotation from the motion of this spot, he made a report of his observations to the Royal Academy of Sciences, and calculated the precise moment when the spot would appear on the eastern limb of the planet, on a future day; on which the academy sent a deputation of M. Buot, M. Mariotte, and others, to be present at the observation; and when they came to the royal observatory, they saw the spot in the position predicted, and traced its motion for an hour or two, until the heavens began to be overcast with clouds. All the observations which have been made upon this spot and others, and its successive appearance and disappearance, perfectly agree with the idea of bright belts inclosing the globe of Jupiter at a distance from the surface, and varying their aspect and motions at different periods of time. And although some readers may consider it as a trifling matter to dwell with such particularity on a spot in Jupiter, yet that spot, however insignificant it may appear through our telescopes, may be more spacious and important in the system of nature than all the continents and islands of our globe, and may form a greater portion of the divine government than all the kingdoms of the earth.

There is a peculiar splendor in the appearance of Jupiter, both through the telescope and to the naked eye, considering his great distance from the sun and from the earth. The planet Mars appears comparatively dull and obscure, even when nearest the earth, when it is only fifty millions of miles distant; while the planet Jupiter, which is 350 millions of miles farther from the earth and from the source of light, presents a brilliancy of aspect far superior. This circumstance seems to indicate that there is some apparatus connected with the globe of Jupiter calculated to reflect the light of the sun in a peculiar manner, both on the surface of the planet itself, on its moons, and toward other planets. Such an apparatus is not only consistent with the supposition thrown out above, but tends to corroborate it; and however strange we may consider the idea of brilliant belts surrounding a planet, yet as *variety* is stamped on all the works of the Creator, and as no world is precisely like another, the dissimilarity of such an appendage to what we know of our own or of other globes ought to be no argument against its existence If we wish to know more of the phenomena of this planet than what we have hitherto ascertained, we must endeavor to improve our telescopes, and to increase, indefinitely, the number of observers. Were an immense number of intelligent observers distributed over different parts of the earth, and provided with the best telescopes; were they to mark with care and minuteness the phenomena to which we have adverted; were they to delineate, in a series of drawings, the various aspects of this planet during two or three periodical revolutions, marking the periods of the different changes, and the positions of the planet with respect to the earth and the sun, and noting at the same time the positions of the satellites when any change in the belts took place, we might possibly ascertain something more of the nature of the belts, whether dark or bright, of the periods of their changes, and whether these changes be influenced by the attractive power of the satellites. For if any appendage is connected with Jupiter composed of a substance of small density, it is reasonable to believe that its positions and movements would be affected at certain times by the positions of the satellites, especially when they all happened to be situated on the same side of Jupiter.

Seasons, Proportion of Light, &c., in Jupiter.--The axis of this planet being nearly perpendicular to the plane of its motion, there can be no variety of seasons similar to what we experience. The inclination of its axis, however, is stated by some astronomers, to be 86 degrees, 54½ minutes; or 3 degrees, 5½ minutes from the perpendicular. This inclination will cause a slight variety of seasons at different periods of the planet's annual revolution, but not nearly to the same extent as in Mars or the earth. If the axis of Jupiter were as much inclined to his ecliptic as the axis of the earth, his polar regions would remain in darkness for nearly six years without intermission, just as the places around our north and south poles are deprived of the light of the sun for one-half of the year. There will be nearly equal day and night in every part of the surface of this planet; but to the places near the equator the sun will appear to rise to a high elevation above the horizon, and to move through the heavens with great rapidity, while near the polar regions he will appear to move comparatively slow, and to describe only a small semicircle above the horizon. We are not to imagine, however, that "everlasting winter" prevails around the poles of this planet, as some have asserted, because the sun never rises high above those regions, and the solar rays fall obliquely upon them; for there may be arrangements and compensations, of which we are ignorant, to produce nearly as great a degree of light and heat in the polar as in the equatorial regions; and perhaps the bright belts to which we have adverted may be so arranged as to contribute to this effect. Nor are we to imagine that there is no *variety of scenery* in Jupiter because there are no seasons similar to ours. For every degree of latitude from the equator to the poles will produce a diversity of aspect; and the variation of the belts, whatever may be their arrangement, and of what substances soever they may consist, will produce a diversity of scenery in the firmament of Jupiter far greater, and, perhaps, far more magnificent and transporting than anything we contemplate in our terrestrial globe.

The *intensity of the solar light* on the surface of Jupiter is twenty-seven times less than on the earth. The mean apparent diameter of the sun, as seen from the earth, is thirty-two minutes, three seconds; but the solar diameter, as seen from Jupiter, is only six minutes, nine seconds, which is less than one-fifth as great as the sun appears to us. The square of 6′ 9″, or 369″, is 136,161, and the square of 32′ 3″ is 369,729, which, divided by 136,161, produces a quotient of 27 1-6, which shows that the surface of the sun, as seen from Jupiter, is more than twenty-seven times less than he appears to us; and as the intensity of light decreases in proportion to the square of the distance, there will be twenty-seven times less light on this planet than on the earth. But if the intensity of the light be increased by reflection from any substances connected with this planet, or if the inhabitants have the pupils of their eyes much larger than ours, all the objects around them may appear with even greater splendor than on the earth. The following figures will show to the eye the proportional size of the sun as seen from Jupiter and from the earth. The small circle shows the comparative bulk of the solar orb as seen from Jupiter, and the larger circle its bulk as viewed from the earth.

Fig. 55.

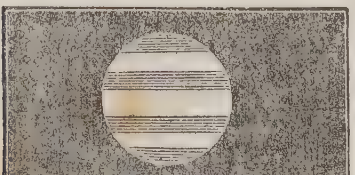


Nothing particular has been ascertained respecting an *atmosphere* surrounding this planet.—Though it is probable that it has an appendage answering the purpose of an atmosphere, yet it may be very different in its nature and properties from that which surrounds the earth. And if the planet be surrounded with bright belts, as we have supposed, or if the bright parts of its surface are to be considered as something analogous to clouds suspended in a body of air, it is evident that the denser parts of its atmosphere never can be perceived by us, and that no dimness or obscurity is to be expected when a fixed star approaches its disc. Hence M. Schroeter, when he had a very clear and distinct view of the spots and belts when Jupiter suffered an occultation by the moon on the 7th of April, 1792, could perceive nothing throughout the whole observation indicative of a refractive medium near the margin of the planet.

Jupiter is remarkable on account of his *spheroidal figure.* This figure is obvious to the eye when viewing the planet with a high magnifying power. Nor is this an optical illusion; for both diameters have been accurately measured by the micrometer; and the equatorial diameter is found to be in proportion to the polar nearly as fourteen to thirteen, so that the equatorial is more than 6300 miles longer than the polar diameter. This oblate figure is ascribed to the swiftness of Jupiter's rotation, which produces a centrifugal force, which has a tendency to make the equatorial parts more protuberant than the polar. From calculations formed on the principles of physical astronomy, it is found that the proportion above stated is really the degree of oblateness which corresponds, on those principles, to the dimensions of this planet and the time of its rotation; so that theory perfectly harmonizes with observation.

The *density* of this planet compared with that of water is as 1 1-24 to 1; that is, it is a small fractional part denser than water. Its *mass*, compared with that of the sun is as 1 to 1067; compared with that of the earth, as 312 to 1; that is, Jupiter could weigh 312 globes of the same size and density as the earth. The *eccentricity* of its orbit is 23,810,000 miles; and the *inclination* of the orbit to the ecliptic is about one degree, nineteen minutes. Its mean *apparent diameter* is thirty-eight seconds, and its greatest diameter, when in opposition to the sun, forty-seven and a half seconds. Its mean arc of retrogradation is nine degrees, fifty-four minutes, and its mean duration about 121 days. This retrogradation, or moving contrary to the order of the signs, commences or finishes when the planet is not more than 115 degrees from the sun. The following figure exhibits a view of Jupiter and his satellites as seen through a good telescope.

Fig. 56.



VII. ON THE PLANET SATURN.

The planet Saturn may be considered in almost every respect as the most magnificent and interesting body within the limits of the planetary system. Viewed in connection with its satellites and rings, it comprehends a greater quantity of surface than even the globe of Jupiter; and its majestic *rings* constitute the most singular and astonishing phenomena that have yet been discovered within the limits of our system.

Its distance from the sun is 906 millions of miles, which is nearly twice the distance of Jupiter; and the circumference of its orbit is 5,695,000,000 of miles; to move round which a cannon ball would require more than 1300 years, although it were moving 500 miles every hour But a steam-carriage, moving at the rate of twenty miles an hour, would require above 32,500 years to complete the same round. When nearest the earth, Saturn is 811 millions of miles distant, an interval which could not be traversed by a carriage, at the rate now stated, in less than 4629 years; and even a cannon ball, moving with the velocity above mentioned, would require 184 years. So that, although man were divested of the gravitating power, and capable of supporting himself amid the ethereal regions, and though he were invested with a power of rapid motion superior to any movement we perceive on earth, before he could reach the middle orbit of the planetary system, or one-fourth of its diameter, it would require a space of time far more than is yet allotted to mortal existence, and, therefore, all hope of personally exploring the celestial regions is completely annihilated, so long as we are invested with our present corporeal vehicles, and are connected with this terrestrial abode.

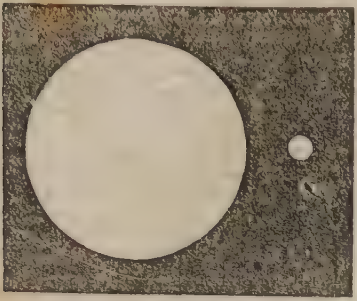
This planet revolves round the sun in the space of about 29½ years, or in 10,758 days, 23 hours, 16 minutes, 34 seconds, which is its *sidereal* revolution, or the time it takes in moving from a certain fixed star to the same star again. Through the whole of its circuit it moves at the rate of 22,000 miles every hour. The period of its rotation was for a long time unknown. About a century ago, it was conjectured by some astronomers that it was accomplished in about ten or eleven hours. It was not, however, until Sir W. Herschel applied his powerful telescopes to Saturn that its rotation was accurately determined. By certain dark spots which he perceived on its disc, and by their change of position, he ascertained that the diurnal rotation is performed in ten hours, sixteen minutes, and nineteen seconds.* It is remarkable that La Place, from physical considerations, had calculated the rotation of Saturn to be nearly the same as above stated, before Herschel had determined it by direct observation. The rotation is performed on an axis perpendicular to the plane of the ring. The circumference of Saturn being 248,000 miles, the parts about the equator will move at the rate of 24,000 miles an hour. Its year will consist of 25,150 days, or periods of its diurnal rotation.

Proportion of Light on Saturn.—This planet being about 9½ times farther from the Sun than the earth, it will receive only the *one-ninetieth* of the light which we receive; for the square of 9½ is equal to 90¼. This quantity of light, however, is equal to the light which would be reflected from a thousand full moons such as ours; and there can be little doubt that the beings that reside in this planet have their organs of vision so constructed as to be perfectly adapted to the quantity of light they receive; and, by such an adaptation, all the objects around them may appear as splendidly enlightened, and their colors as vivid as they do on the globe on which we live. The apparent diameter of the sun, as seen from Saturn, is three minutes, twenty-two seconds; but his mean apparent diameter, as seen from the earth, is equal to thirty-two minutes, three seconds. This proportion of size in which the sun appears from the earth and from Saturn is represented in the following figure, in which the small circle represents the size of the sun as seen from Saturn.

---

* Sir John Herschel states the period of rotation to be ten hours, twenty-nine minutes, seventeen seconds.

Fig. 57.



Discoveries by the Telescope on the Body of Saturn.—The great distance of this planet from the earth prevents us from observing its surface so minutely as that of Jupiter. Certain dusky spots, however, have of late years been occasionally seen on its surface, when very powerful telescopes were applied, and by the motion of these its diurnal rotation was determined. Belts somewhat similar to those of Jupiter have likewise been seen. Huygens, more than 150 years ago, states that he had perceived five belts on Saturn which were nearly parallel to the equator. Sir W. Herschel, in his numerous observations, also observed several belts, which in general, were parallel with the ring. On the 11th of November, 1798, immediately south of the shadow of the ring upon Saturn, he perceived a bright, uniform, and broad belt, and close to it a broad or darker belt, divided by two narrow white streaks, so that he saw five belts, three of which were dark and two bright. The dark belt had a yellow tinge. These belts cover a larger zone of the disc of the planet than the belts of Jupiter occupy upon his surface. With a magnifying power of 200 times I have sometimes seen one darkish belt on the body of Saturn; but it was much fainter than those of Jupiter. It does not appear that these belts vary or shift their positions, as the belts of Jupiter are found to do; the dark ones are much fainter than those of Jupiter, and, therefore, it is most probable that they are permanent portions of the globe of Saturn, which indicate a diversity of surface and configuration either of land or water, or of some other substances with which we are unacquainted. When this planet is viewed with a good telescope, it appears, like Jupiter, to be of a spheroidal figure, or somewhat approaching to it. The proportion of its polar to its equatorial diameter is as 32 to 35, or nearly as 11 to 12; so that the polar diameter is more than 6,700 miles shorter than the equatorial, which is a greater difference than that of the two diameters of Jupiter. Saturn was generally considered, until lately, as a regular spheroid; but on the 12th of April, 1805, Sir W. Herschel was struck with a very singular appearance when viewing the planet. "The flattening of the poles did not seem to begin until near a very high latitude, so that the real figure of the planet resembled a square, or rather a parallelogram, with the four corners rounded off deeply, but not so much as to bring it to a spheroid." It is probable that the action of the ring or its attractive power is the cause of the great protuberance which is found about the equatorial regions of Saturn.

Magnitude and Extent of Surface on Saturn.—This planet is about 79,000 miles in diameter, and nearly a thousand times larger than the earth. Its surface contains more than 19,600,000,000 of square miles, and, consequently, at the rate of 280 inhabitants to a square mile, it would contain a population of 5,488,000,000,000, or about five billions and a half, which is six thousand eight hundred and sixty times the present number of inhabitants on our globe; so that this globe, which appears only like a dim speck on our nocturnal sky, may be considered as equal to six thousand worlds like ours; and since such a noble apparatus of rings and moons is provided for the accommodation and contemplation of intelligent beings, we cannot doubt that it is replenished with ten thousand times ten thousands of sensitive and rational inhabitants; and that the scenes and transactions connected with that distant world may far surpass in grandeur whatever has occurred on the theater of our globe.

Density of Saturn.—The density of Saturn, compared with that of the earth, is nearly as one to nine; compared with that of water, it is less than one-half; so that the mean density of this planet cannot be much more than the density of cork; and, consequently, the globe of Saturn, were it placed in an immense ocean, would swim on the surface as a piece of cork or light wood swims in a basin of water. There is none of the planets, so far as we know, whose density is so small as that of Saturn, or less than the density of water. We are not to imagine, however, that the materials which compose the surface of Saturn are as light as cork, or similar substances; for anything we know to the contrary, they may be as dense as the rocks and mold which compose the crust of our globe. We have only to suppose that the globe of Saturn is hollow, or merely filled with some elastic fluid, and that the solid parts of its exterior crust form a shell of a hundred or two hundred miles in thickness. It is true, indeed, that the density of our globe increases from its surface downward, perhaps even to the center. But we have no reason to suppose that this is the case with all the other planets; on the contrary, it is most probable that it is exactly the reverse in the case of Saturn; for if the materials which compose that planet were to increase in density toward the center, the substances on its surface would have little more density or solidity than that of a cloud suspended in the atmosphere. And we know that, in all the works of the Creator, *variety* is one grand characteristic of his plans, even where the same general objects are intended to be accomplished, and the same *general* laws are in operation.

From want of correct views on this subject, several foolish and erroneous notions have been entertained and circulated. In a late number of a popular and extensively circulated journal, when treating of "Planetary Arrangements," it is stated, that "while on Mercury a native of earth would scarcely be able to drag one foot after another for the strong power pulling him to the ground, he could, on the planet Saturn, leap sixty feet high as easily as he could here leap a yard." Now, both these positions are quite erroneous; for although the density of Mercury is about double the density of the earth, and nearly that of lead, yet the bulk of the two planets is very different, the diameter of the earth being nearly 8000 miles, while that of Mercury is only 3200, and the force with which a body placed on their surfaces gravitates to them is in proportion to their *masses* divided by the *squares of their diameters.* If Mercury were as large as the earth, an inhabitant of our globe placed on the surface of that planet would feel himself "pulled to the ground" as if he were placed on a similar ball of lead, and his weight, of course, would be increased; but, as matters now stand, the gravitation on Mercury is only a small fraction greater than on the surface of the earth; so that, in this respect, "a native of the earth," and particularly an inhabitant of Greenland, might walk with nearly as much ease on the planet Mercury as under our equator. The same considerations show the absurdity of what is stated in relation to Saturn; for that planet is ten times the diameter of the earth; and though its density is nearly as small as that of cork, yet its immense bulk renders the force of gravity at its surface somewhat greater than even on the earth, and almost as great as on the surface of Mercury. A body which weighs one pound on the surface of the earth would weigh one pound and four drachms if removed to the surface of Saturn; so that a person, instead of being able to "leap sixty feet high" from the surface of this planet, would be unable to leap quite so high as he can do on the earth. In short, there is not a planet in the solar system, with the exception of Jupiter, on which an inhabitant of the earth might not move about as easily, in respect to gravitating power, as he does on the terraqueous globe; and even on Jupiter, he would experience little more than double the weight he now feels. On some of the other planets, such as Mars and Juno, he would feel somewhat lighter than he now does, but not nearly so much as would enable him to leap to such a hight as above stated. On the same principle, which is taken for granted in the above quotation, we might suppose that a person would feel much lighter were he placed on the surface of the sun, because the density of that luminary is little more than the density of water; whereas, in consequence of his immense size, the gravitating power would be *twenty-seven* times greater than at the surface of our globe. For, according to the calculations of La Place, a body which, at the earth's equator, weighs one pound, if transported to the surface of the sun, would weigh about twenty-seven and a half pounds; from which it follows, that there a heavy body would descend about four hundred and twenty-five feet in the first second of time; consequently, were a man who weighs two hundred pounds to be placed on the sun, he would be pressed down to its surface with a force equal to five thousand five hundred pounds, or nearly two tons and a half, which would fix him to the surface without power of motion. So that whatever beings may inhabit that globe, it is not fitted for the residence of man in his present state of organization.

The *eccentricity* of Saturn's orbit is 49,000,000 of miles, which is about the 1-37th part of the diameter of the orbit. Its inclination to the ecliptic is 2° 29½′. Its apparent diameter, as seen from the earth, is seventeen minutes, six seconds; and its mean daily motion, two minutes of a degree.

VIII. ON THE RINGS OF SATURN.

Beside the appearance above described, this planet is encircled with a double ring, one of the most astonishing phenomena which have yet been discovered in the heavens, and which, therefore, requires a separate and particular description.

The first individual who perceived a glimpse of Saturn's ring was Galileo, soon after the invention of the telescope. He thought he saw that planet appear like two smaller globes on each side of a larger globe; or, as he expressed it, that "Saturn was in the shape of an olive." In the year 1610, he published his discovery in a Latin sentence, the meaning of which was, that he had seen Saturn appear *with three bodies.* After viewing Saturn in this form for two years, he was surprised to see him become quite round without his adjoining globes, and to remain in this state for some time, and, after a considerable period, to appear again in his triple form as before. This deception was owing to the want of magnifying power in the telescope used by Galileo; for the first telescope constructed by this astronomer magnified the diameters of objects only three times; his second improved telescope magnified only eight times; and the best telescope which, at that time, he found himself capable of constructing, magnified little more than *thirty times;* and with this telescope he made most of his discoveries. But a telescope of this power is not sufficient to show the opening or dark space between the ring and Saturn on each side of the planet; and at the time when it appeared divested of its two appendages, the thin and dark edge of the ring must have been in a line between his eye and the body of Saturn, which phenomenon happens once every fifteen years. About forty years after this period, the celebrated Huygens greatly improved the art of grinding object glasses; and with a telescope of his own construction, twelve feet long, and afterward with another of twenty-three feet, which magnified objects one hundred times, he discovered the true shape of Saturn's ring, and in 1659 he published his "*Systema Saturnium,*" in which he describes and delineates all its appearances.

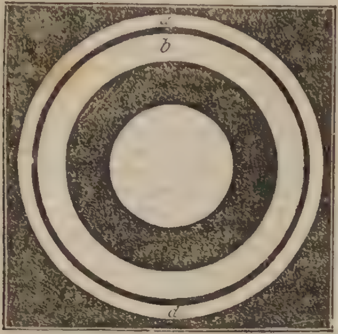
It was suspected by astronomers more than a century ago, that the ring of Saturn was double, or divided into two concentric rings. Cassini supposed it probable that this was the case. Mr. Pound, in the account of his observations on Saturn in 1723, by means of Hadley's new reflecting telescope, states that with this instrument he could plainly perceive "*the black list in Saturn's ring,*" and gives an engraving of the planet and ring with this dark stripe distinctly marked, as in the modern views of Saturn.* Mr. Hadley likewise states† that, in the year 1722, with the same telescope, he observed the dark line on the ring of Saturn parallel to its circumference, which was chiefly visible on the ansæ, or extremities of the elliptic figure in which the ring appears, but that he was several times able to trace it quite round; particularly in May, 1722, he could discern it without the northern limb of Saturn, in that part of the ring that appeared beyond the globe of the planet, and could perceive that the globe of Saturn reflects less light than the inner part of the ring. It was not, however, until Sir W. Herschel began to make observations on this planet with his powerful telescopes, that Saturn was recognized as being invested with two concentric rings. The following cut (Fig. 58) exhibits a view of Saturn and his rings, nearly in their respective proportions, as they would appear were they placed perpendicular to our line of sight; but, on account of the oblique angle they generally form to our line of vision, we never see them through the telescope in this position.

---

* See "*Philosophical Transactions,*" No. 378, for July, 1723; and Reid and Gray's Abridgment, Vol. vi, p. 153.

† "*Philosophical Transactions,*" No. 378; or Abridgment, Vol. vi, p. 154.

Fig. 58.



The following are the dimensions of the rings, as determined by the observations of Sir W. Herschel, which are here expressed in the nearest round numbers. Outside diameter of the *exterior* ring, *a d*, 204,800 miles, which is nearly twenty-six times the diameter of the earth. Inside diameter of this ring, 190,200 miles; breadth of the dark space between the two rings, 2839 miles, which is 700 miles more than the diameter of our moon, so that a body as large as the moon would have room to move between the rings. Outside diameter of the *interior* ring, *b*, 184,400, and the inside diameter, 146,300 miles. *Breadth* of the exterior ring, 7200 miles; breadth of the interior, 20,000 miles, or 2½ times the diameter of the earth; so that the interior ring is nearly three times broader than the exterior. The *thickness* of the rings has not yet been accurately determined. Sir John Herschel supposes that it does not exceed a hundred miles. "So very thin is the ring," says Sir John, "that it is quite invisible, when its edge is directly turned to the earth, to any but telescopes of extraordinary power." On the 19th of April, 1833, "the disappearance of the rings was complete when observed with a reflector eighteen inches in aperture and twenty feet in focal length.[*] The breadth of the two rings, including the dark space between them, is very nearly equal to the dark space which intervenes between the globe of Saturn and the inside of the interior ring. It appears to have been lately ascertained that this double ring is not exactly circular, but eccentric. This seems to have been first observed by M. Schwalz, of Dessau, in 1828. He informed M. Harding of it, who thought he saw the same thing; M. Harding informed Professor Schumacher, who applied to M. Strüve to settle the question by means of the superb micrometer attached to his great telescope. M. Strüve measured the distance between the ring and the body of the planet on five different days, and ascertained that *Saturn's ring is really eccentric*, and, consequently, that the center of the planet does not coincide with the center of the ring; but that the center of gravity of the rings oscillates round that of the body of Saturn, describing a very minute orbit. This is considered as of the utmost importance to the *stability* of the system of the rings, in preventing them from being shifted from their equilibrium by any external force, such as the attraction of the satellites, which might endanger their falling upon the planet. That this double ring really consists of two concentric rings, was demonstrated, says Professor Robison, "by a star having been seen through the interval between them."

This double ring is now found to have a swift rotation round Saturn in its own plane, which it accomplishes in about ten hours and a half. This is very nearly the periodic time which a satellite would take in revolving at the same distance from the center of Saturn. This rotation was detected by observing that some portions of the ring were a little less bright than others. Sir W. Herschel, when examining the plane of the ring with a powerful telescope, perceived near the extremity of its arms or *ansæ* several lucid or protuberant points, which seemed to adhere to the ring. At first he imagined them to be satellites, but afterward found, upon careful examination, that none of the satellites could exhibit such an appearance, and therefore concluded that these points adhered to the ring, and that the variation in their position arose from a rotation of the ring round its axis in the period above stated. The circumference of the exterior ring being 643,650 miles, every point of its outer surface moves with a velocity of more than a thousand miles every minute, or seventeen miles during one beat of the clock. It is highly probable that this rapid rotation of the ring is one of the principal causes, under the arrangements of the Creator, of *sustaining* the ring, and preventing it from collapsing and falling down upon the planet. This double ring is evidently a *solid* compact substance, and not a mere cloud or shining fluid; for it casts a deep shadow upon different regions of the planet, which is plainly perceived by good telescopes. Beside, were it not a solid arch, its centrifugal force, caused by its rapid rotation, would soon dissipate all its parts, and scatter them in the surrounding spaces. It is not yet ascertained whether both the rings have the same period of rotation. This magnificent appendage to the globe of Saturn is about 30,000 miles distant from the surface of the planet, so that four globes nearly as large as the earth could be interposed between them; it keeps always the same position with respect to the planet; is incessantly moving around it; and is carried along with the planet in its revolution round the sun.

The surface of the double ring does not seem to be exactly plane. One of the ansæ[*] sometimes disappears and presents its dark edge, while the other ansa continues to appear, and exhibits a part of its plane surface. On the 9th of October, 1714, the ansæ appeared twice as short as usual, and the eastern one much longer than the western. On the first of the same month, the largest ansa was on the east side; on the 12th, the largest ansa was on the west side of Saturn's disc;[†] which led the observers, even at that period, to conclude that the ring had a rotation round the planet. On the 11th of January, 1774, M. Messier observed both the ansæ completely detached from the planet, and the eastern one larger than the other. In 1774, Sir W. Herschel likewise observed Saturn with a single ansa. From these observations, it has been concluded that there are irregularities on the surface of the ring, analogous, perhaps, to mountains and vales of vast extent; and that the occasional disappearance of the ansæ may possibly arise from a curvature in its surface. Sir W. Herschel was of opinion that the *edge* of the exterior ring is not flat, but of a spherical, or rather spheroidal form.

---

[*] Sir John Herschel states the dimensions of these rings on a somewhat lower scale than what his father determined. He says that they were calculated from Professor Struve's micrometrical measures; but admits that some of the dimensions he states are perhaps too small.

[*] The parts of the ring about the ends of the longest axis, reaching beyond the disc of the planet, are called the *ansæ*. Ansa signifies a *handle*, which name was given when telescopes were so imperfect as to represent Saturn as a globe with two small knobs on each side. The same name is still continued, though it is somewhat improper, now that the true shape of this appendage is known. Still the general appearance of Saturn is somewhat like a globe, with an ansa or handle on each side.

[†] Memoirs of the Royal Academy of Sciences for 1715.

Dimensions of Saturn's Rings.—It is difficult for the mind to form an adequate conception of the magnitude, the mechanism, and the magnificence of these wonderful rings, which form one of the most astonishing objects that the universe displays. In order to appreciate, in some measure, the *immense size* of these rings, it may be proper to attend to the following statements: Suppose a person to travel round the outer edge of the exterior ring, and to continue his journey without intermission at the rate of twenty-five miles every day, it would require more than *seventy years* before he could finish his tour round this immense celestial arch. The interior boundary of the *inner* ring incloses a space which would be sufficient to contain within it three hundred and forty globes as large as the earth; and the *outer* ring could inclose within its inner circumference five hundred and seventy-five globes of the same magnitude, supposing every portion of the inclosed area to be filled. This outer ring would likewise inclose a globe containing 2,829,580,622,048,315 or more than two thousand eight hundred *billions* of cubical miles, which globe would be equal to more than *ten thousand eight hundred globes* of the size of the earth. In regard to the *quantity of surface* contained in these rings, the one side of the outer ring contains an area of 4,529,401,800, or more than four thousand five hundred millions of square miles. The one side of the inner ring contains 9,895,780,818, or nearly ten thousand millions of square miles. The two rings, therefore, contain on one side above fourteen thousand four hundred millions of square miles; and as the other sides of the rings contain the same extent of surface, the whole area comprehended in these rings will amount to 28,850,365,236, or more than twenty-eight thousand eight hundred millions of square miles. This quantity of surface is equal to 146 times the number of square miles in the terraqueous globe, and is more than 588 times the area of all the habitable portions of the earth. Were we to suppose these rings inhabited (which is not at all improbable) they could accommodate a population, according to the rate formerly stated, of 8,078,102,266,080, or more than *eight billions*, which is equal to more than *ten thousand times* the present population of our globe; so that these rings, in reference to the space they contain, may be considered, in one point of view, as equal to ten thousand worlds.

Were we to take into consideration the *thickness* of the rings, we should find a very considerable addition to the area above stated. Supposing, according to Sir J. Herschel's estimate, that they are only one hundred miles thick, the area of the exterior circumference of the edge of the *outer* ring will be 64,365,700 miles; and that of the interior edge, 59,777,100. The exterior edge of the *inner* ring will contain an area of 57,954,200 square miles, and the interior edge 45,980,000; in all 228,077,000 square miles, which is thirty-one millions of square miles more han the whole area of our globe.

These rings, therefore, exhibit a striking idea of the *power* of the Creator, and of the grandeur and magnificence of his plans and operations. They likewise display the depths of his *wisdom* and intelligence; for they are so adjusted, both in respect to their position around the body of the planet and to the degree of motion impressed upon them, as to prevent both their falling in on the planet and their flying off from it through the distant regions of space. We have already stated that the rings are not exactly concentric with the body of the planet. Now, it is demonstrable, from physical considerations, that were they mathematically perfect in their circular form, and exactly concentric with the planet, "they would form a system in a state of *unstable equilibrium*, which the slightest external power," such as the attraction of the satellites, "might completely subvert, by precipitating them unbroken on the surface of the planet." For physical laws must be considered as operating in the system of Saturn as well as in the earth and moon, and the other planets; and every minute circumstance must be adjusted so as to correspond with these laws. "The observed oscillation," says Sir J. Herschel, "of the centers of the rings about that of the planet is, in itself, the evidence of a perpetual contest between conservative and destructive powers, both extremely feeble, but so antagonizing one another as to prevent the latter from ever acquiring an uncontrollable ascendency and rushing to a catastrophe." "The smallest difference of velocity between the body and rings must infallibly precipitate the latter on the former, never more to separate; consequently, either their motions in their common orbit around the sun must have been adjusted to each other by an external power with the minutest precision, or the rings must have been formed about the planet while subject to their common orbitual motion and under the full free influence of all the acting forces." Here, then, we have an evident proof of the consummate wisdom of the almighty Contriver in so nicely adjusting everything in respect to number, weight, position and motion, as to preserve in undeviating stability and permanency this wonderful system of Saturn; and we have palpable evidence that everything conducive to this end has been accomplished, from the fact that no sensible deviation has been observed in this system for more than 220 years, or since the ring was discovered; nor, in all probability, has there ever been any change or catastrophe in this respect since the planet was first created and launched into the depths of space.

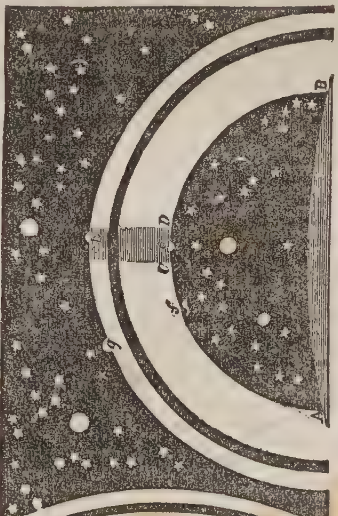
Appearance of the Rings from the body of Saturn.—These rings will appear in the firmament of Saturn like large luminous arches or semicircles of light, stretching across the heavens from the eastern to the western horizon, occupying the one-fourth or one-fifth part of the visible sky.—As they appear more brilliant than the body of the planet, it is probable that they are composed of substances fitted for reflecting the solar light with peculiar splendor, and therefore, will present a most magnificent and brilliant aspect in the firmament of Saturn. Their appearance will be different in different regions of the planet. At a little distance from the equator they will be seen nearly as complete semicircles, stretching along the whole celestial hemisphere, and appearing in their greatest splendor. In the day-time they will present a dim appearance, like a cloud or like our moon when the sun is above the horizon.—After sunset their brightness will increase, as our moon increases in brilliancy as the sun disappears, and the shadow of the globe of Saturn will be seen on their eastern boundary directly opposite to the sun. This shadow will appear to move gradually along the rings until midnight, when it will be seen near the zenith, or the highest point of these celestial arches. After midnight it will appear to decline to the western horizon, where it will be seen near the time of the rising of the sun. After sunrise the brightness decays, and it appears like a cloudy arch throughout the day. The following circumstances will add to the interest of this astonishing spectacle: 1. The *rapid motion* of the rings, which will appear to move from the eastern horizon to the zenith in two hours and a half. 2. The *diversity of surface* which the rings will exhibit; for if we can trace inequalities upon these rings by the telescope at the distance of more than 800,000,000 of miles, much more must the inhabitants of Saturn perceive all the variety with which they are adorned when they are placed so near them as the one-eighth part of the distance of our moon. Every two or three minutes, therefore, a new portion of the scenery of the rings will make its appearance in the horizon with all their diversified objects; and if these rings be inhabited, the various scenes and operations connected with their population might be distinguished from the surface of Saturn with such eyes as ours, aided by our most powerful telescopes. 3. The motion of the shadow of the globe of Saturn in a direction contrary to the motion of the rings, which shadow will occupy a space of many thousand miles upon the rings, will form another variety of scenery in the firmament. 4. If the two rings revolve around the planet in different periods of time, the appearance in the celestial vault will be still more diversified; then one scene will be seen rising on the upper, and another and a different scene rising on the lower ring; and, through the opening between the rings, the stars, the planets, and one or two of the satellites may sometimes appear.

Near the polar regions of the planet only a comparatively small portion of the rings will appear above the horizon, dividing the celestial hemisphere into two unequal parts, and presenting the same general appearance now described, but upon a smaller scale. Toward the polar points the rings will, in all probability, be quite invisible. During the space of fourteen years and nine months, which is half the year of this planet, the sun shines on the one side of these rings without intermission, and during the same period he shines on the other side. During nearly fifteen years, therefore, the inhabitants on one side of the equator will be enlightened by the sun in the day-time and the rings by night, while those on the other hemisphere, who live under the dark side of the ring, suffer a solar eclipse of fifteen years' continuance, during which they never see the sun.—At the time when the sun ceases to shine on one side of the ring, and is about to shine on the other, the rings will be invisible for a few days or weeks to all the inhabitants of Saturn.

At first view we might be apt to suppose that it must be a gloomy situation for those who live under the shadow of the rings during so long a period as fifteen years; but we are not acquainted with *all the circumstances* of their situation, or the numerous beneficent contrivances which may tend to cheer them during this period, and, therefore, are not warranted to conclude that such a situation is physically uncomfortable. We know that they enjoy the light of their moons without almost any interruption; sometimes two, sometimes four, and sometimes all their seven moons are shining in their hemisphere in one bright assemblage. Beside, during this period is the principal opportunity they enjoy of contemplating the starry firmament, and surveying the more distant regions of the universe, in which they may enjoy a pleasure equal, if not superior, to what is felt amid the splendor of the solar rays; and it is not improbable that multitudes may resort to these darker regions for the purpose of making celestial observations; for the bright shining of the rings during the continuance of night will, in all probability, prevent the numerous objects in the starry heavens from being distinguished. The very circumstances, then, which might, at first view, convey to our minds images of gloom and horror, may be parts of a system in which are displayed the most striking evidences of beneficent contrivance and design. It must be a striking scene when the sun is of a sudden altogether intercepted, without any apparent cause, not to return for fifteen years; and, on the other hand, when, at the end of this period, his light again bursts all at once upon the astonished beholders, closing up, as it were, the prospects of the firmament, and diffusing his splendor on every surrounding object; and both events may be attended with sentiments of admiration and emotions of delight. At certain times of the year of Saturn, and in certain latitudes from his equator, the sun will be eclipsed for a short time, every day at noon, by the upper part of the exterior ring, according as he declines more or less to the opposite side; and sometimes he will be partially eclipsed by the under side of the exterior ring and the upper side of the interior, and sometimes will be seen moving along the interval which separates these rings.

The following figures are intended to convey a rude idea of the objects connected with the firmament of Saturn.

Fig. 59.



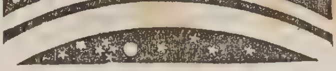


Fig. 60.

Fig. 59, represents the appearance of the rings at a little distance from the planet's equator, where they will appear nearly as complete semicircles. *A B* represents a portion of the globe of Saturn; *C D* the shadow of Saturn as it appears upon the rings at midnight, after which it will appear to move gradually to the west until sunrise, when it will disappear below the horizon. The sun, partly eclipsed by the upper and lower edge of the rings in the day-time, is represented at *e*, *f*, *g*, and *h*. The other objects are some of the satellites in different phases, and the fixed stars, of which few will probably be seen, some of them within and some of them beyond the rings.—Fig. 60, represents the rings as they will appear from places near the polar regions of the planet, from which situations they will appear as only small segments of circles near the horizon. The nearer the pole, the smaller the circles will appear.

From the above description, it appears that there is a great *variety* in the scenery presented in the firmament of Saturn; and this scenery is different as viewed from different regions of the planet. From the regions near the equator the rings will appear to the greatest advantage and in all their splendor. From these positions the various objects connected with the rings will be most distinctly observed, as the spectators will be at the nearest distance from the inner ring, which is about thirty thousand miles. At the latitude of 45° they will be twenty thousand miles farther from them; they will appear at a much lower elevation above the horizon, a smaller portion of their curve will be seen, and their *breadth* will occupy a less space in the heavens. At a higher latitude a still smaller portion will be seen, until they dwindle to a small curve or speck of light in the horizon; and at the poles they will be quite invisible by the interposition of equatorial parts of the planet. Immediately under the equator the light of the rings will be scarcely visible, but the sun will occasionally illuminate the under edge of the interior ring, at *f*, *e*, *D*, and other places; which, at night, will appear like a narrow luminous arch stretching directly across the zenith from the eastern to the western horizon, and diversified with the motion of the shadow of Saturn. Beside the different appearances of the starry regions, the various aspects of the moons, some of them rising, setting, and culminating,* some of them appearing as crescents, half moons, and full enlightened hemispheres, some entering into an eclipse, and some emerging from it, and all of them appearing to move with a rapid velocity around the sky, will greatly add to the *variety* and diversity of scenery which appears in the firmament of this planet. This diversity of aspect, which the scenery of nature presents from different regions of the planet, will, in all probability, have a tendency to promote frequent intercourses among the different tribes of its inhabitants, in order to contemplate the different scenes of nature and providence displayed throughout this spacious and magnificent globe. All these circumstances, properly considered, form of themselves a presumptive argument to prove that the sublime and exquisite contrivances connected with this planet were not intended merely to illuminate barren sands and hideous deserts, but to afford a comfortable and magnificent habitation for thousands of millions of rational inhabitants who employ their faculties in the contemplation of the wonders which surround them, and give to their Creator the glory which is due to his name.

It has often been asked as a mysterious question, "What is the *use* of the rings with which Saturn is environed?" This is a question which I conceive there is no great difficulty in answering. The following considerations will go a great way in determining this question: 1. They are intended to produce all the varieties of celestial and terrestrial scenery which I have described above, and doubtless other varieties with which we are unacquainted; and this circumstance of itself, although we could devise no other reason, might be sufficient to warrant the Creator to deviate from his general arrangements in respect to the other planets. For *variety* is one characteristic of his plans and operations, both in respect to the objects on our globe and to those which exist throughout the planetary system, and it is accordant with those desires for novelty and variety which are implanted in the minds of intelligent beings. 2. They are intended to give a display of the *grandeur* of the Divine Being, and of the effects of his Omnipotence. They are also intended to evince his inscrutable wisdom and intelligence in the nice adjustment of their motions and positions, so as to secure their stability and permanency in their revolutions, along with the planet, around the sun. 3. They are doubtless intended to teach us what varied scenes of sublimity and beauty the Deity has introduced or may yet introduce into various regions throughout the universe. We are acquainted with only a few particulars respecting *one* planetary system; but we have every reason to conclude that many millions of similar or analogous systems exist throughout the unlimited regions of space. In some of those systems the arrangements connected with the worlds which compose them may be as different from those of our globe and some of the other planets, as the arrangements and apparatus connected with Saturn are different from those of the planet Vesta or Mars. Around some of these worlds there may be thrown not only two concentric rings, but rings standing at right angles to each other, and inclosing and revolving round each other; yea, for aught we know, there may be an indefinite number of rings round some worlds, and variously inclined to each other, so that the planet may appear like a terrestrial globe suspended in the middle of an armillary sphere; and all those rings may be revolving within and around each other in various directions and in different periods of time, so as to produce a variety and sublimity of aspect of which we can form no adequate conception. There is nothing irrational or extravagant in these suppositions; for, had we never discovered the rings of Saturn, we could have formed no conception of such an appendage being thrown around any world, and it would have been considered in the highest degree improbable and romantic had any one broached the idea. We are therefore led to conclude, from the characteristic of *variety* impressed on the universe, that Saturn is not the only planet in creation that is surrounded with such an apparatus, and that the number and position of its rings are not the only models according to which the planetary arrangements in other systems may be constructed.

4. Beside the considerations now stated, the chief use, I presume, for which these rings were created was, *that they might serve as a spacious abode for myriads of intelligent creatures*. If we admit that the globe of Saturn was formed for the reception of rational inhabitants, there appears no reason why we should not also admit that the rings were constructed chiefly for the same purpose. These rings, as we have already seen, contain a surface of about *thirty thousand millions* of square miles; and, if all the other planets be inhabited, it is not likely that the Creator would

---

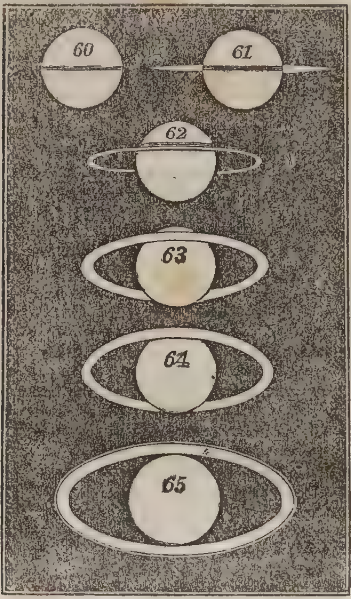
* A heavenly body is said to culminate when it comes to the meridian, or the highest point of its diurnal course.

eave a space equal to nearly 600 times the habitable parts of our globe as a desolate waste, without any tribes of either sensitive or intelligent existence. It forms no objection to this idea that the rings are *flat*, and not globular like the planets; for the Creator can arrange any figure of a world into a suitable abode for intelligent beings; and on our globe we find myriads of animated beings fitted for every mode of existence, and in situations where we should scarcely ever have expected to see them. Beside, three or four centuries have scarcely elapsed since the earth was generally considered as a *plane* indefinitely extended; and the idea of its being a globe, inhabited on all sides, was scouted as untenable, and considered far more ridiculous than it can be now to suppose the flat rings of Saturn as serving the purpose of a habitable world. What should hinder them from serving this purpose as well as the globe of Saturn? They are *solid* arches, which is evident from their shadows and their rapid motion; they contain an ample space for an immense population; they have the power of attraction, like other material substances connected with the solar system; they are capable of being adorned with as great a diversity of surface, and as great a variety of beautiful and sublime objects, as this earth or any other of the planetary bodies; and it can make no great difference in the enjoyments of sentient and intellectual beings whether they live on a globe, a spheroid, a cylinder, or a plane surface, which the hand of Wisdom and Omnipotence has prepared for their reception; while it displays, at the same time, the variety of modes in which the Universal Parent can convey happiness to his numerous offspring. It may, perhaps, be objected to the idea of the habitability of these rings, that, while one side is enlightened during fifteen years without intermission, the other side remains in the dark during the same period. But the same thing happens to extensive regions on the globe of Saturn; and, doubtless, arrangements are made for the enjoyment of the inhabitants in both cases during this period. They enjoy in succession, and sometimes all at once, the light reflected from at least seven moons, and they behold occasionally the body of Saturn reflecting the solar rays from certain parts of its surface, and appearing like a vast luminous crescent, in different degrees of luster, suspended in the sky. (See p. 69.)

Many other views and descriptions might be given of the phenomena connected with the system of Saturn, were it not that I do not wish to exhaust the patience of the reader by dwelling too long on one subject. The circumstance of two concentric rings being thrown around a planet, however simple it may at first sight appear, involves in it an immense variety of peculiar and striking phenomena, in regard both to the inhabitants of the planet and of the rings, so that it is difficult for the mind to form a precise and definite conception of every particular. To acquire even a general view of such phenomena, it would be requisite to construct a pretty large machine, representing the system of Saturn, in all its known motions and proportions, and to make it revolve around a central light. An instrument of this kind is as necessary for illustrating the subject on which we have been descanting, as an orrery or planetarium to illustrate the seasons and the planetary motions.

Telescopic Views of Saturn and its Rings.—As these rings present a variety of aspects as seen from different parts of the planet, so they appear to assume a different appearance at different times when viewed through our telescopes. Sometimes the planet appears to be completely divested of its rings; sometimes they appear only like a short luminous line or streak on each sideof its body; sometimes they appear like handles on each side of the planet; and at other times like a large ellipse or oval almost surrounding the body of the planet. These varied aspects of the rings are owing to the following circumstances. The rings never stand at right angles to our line of vision; otherwise we should see them as represented in Fig. 58 (p. 67). Our eye is never elevated more than thirty degrees above the plane of the rings. The *plane* of these rings preserves a position parallel to itself in every part of the planet's revolution, being constantly inclined at the same, or nearly the same angle to the orbit and to the ecliptic, which angle is about twenty-nine or thirty degrees. The *nodes of the rings* lie in 190° and 350° of longitude, which correspond to the twentieth degree of Virgo and the twentieth of Pisces. When, therefore, the planet is in these points, the rings entirely disappear, because the thin edge of the outer ring only is turned toward our eye, and every trace of it is lost for some time, except the shadow of it, which appears like a dark belt across the planet. This disappearance happens once every fifteen years, but frequently with different circumstances. Two disappearances and two reappearances may occur in the same year, but never more. When Saturn is in the longitude above stated, the plane of the rings passes through the sun, and, the light then falling upon it edgewise, it is to us no longer visible. The rings likewise disappear when their plane passes through the earth; for its edge being then directed to the eye, and being too fine to be seen, the planet appears quite round and unaccompanied with its rings. When the earth is placed on the side of the rings which is turned from the sun, we have a third cause of its disappearance. As the planet passes from the ascending to the descending node of the rings, the *northern* side of their plane is turned toward the sun. As it passes from the descending to the ascending node, the *southern* side of the rings is enlightened. In proportion as it recedes from these nodes, the rings appear to widen and to present a broader ellipsis, until it arrives at 90° from either node, or in 80° or 260° of longitude, corresponding to 20° of Gemini and 20° of Scorpio; at which time the rings will be seen to the greatest advantage, and appear almost surrounding the globe of Saturn. At the time of the greatest opening of the rings, their shorter diameter appears exactly one-half of the longer diameter.

The following figures represent the different appearances of the rings, during half the period of the revolution of Saturn, as seen through good telescopes. Fig. 60 shows the appearance of Saturn when the plane of the ring is parallel to the line of vision, and its thin edge turned to the eye. In this manner the planet appeared during the months of October, November, and part of December, 1832, when nothing was perceptible except the dark shade across its disc, as represented in the figure. The first time the weather permitted observations on Saturn about this period was December 27, when I perceived the ring, with a power of 180, appearing like a fine thread of light on each side of the planet, as represented Fig. 61. About the beginning of October the plane of the ring passed through the center of the sun. At that time the inhabitants of Saturn, who had previously been in darkness, would perceive the margin of the sun projecting over the edge of the ring like a brilliant streak of light, and, in the course of about four of our days, or nine days of Saturn, the whole body of the sun would appear above the plane of the ring, gradually rising a little higher every day, as he does after the 21st March to the north pole of the earth. The ring began to appear a little larger during the months of January, February, and March, 1833; but in April it again disappeared, as the earth was then in the plane of the ring, and it continued invisible until near the end of June. After which it again appeared, as represented in Fig. 61, and will now continue visible until the year 1847, when it will again disappear. In about a year after its second disappearance, it appeared as in Fig. 62. In about a year and a half afterward the opening between the rings appeared wider, as in Fig. 63; and in 1837 it appeared as in Fig. 64. In Fig. 65 the rings are represented at the utmost extent in which they are ever seen, along with the dark space that separates the two rings, which can only be distinguished by a telescope magnifying from 220 to 300 times. In this position it will be seen in 1840; after which it will pass through all the gradations here represented, appearing narrower every year until 1847, when it will be seen as in Fig. 61; soon after which it will entirely disappear, and the planet will be seen as if divested of its ring, as represented in Fig. 60. Such are the various aspects under which Saturn and his rings appear, as viewed through powerful telescopes.



IX. ON THE PLANET URANUS.

Since the time of Newton, when the physical causes of the celestial motions began to be studied and investigated, astronomers have had their attention directed to the power or influence which the planetary bodies exert upon each other. This power is termed attraction or gravitation, and is inherent in all material substances, so far as our knowledge extends. It is exerted in proportion to the quantity of matter and the distances of the respective bodies; the planets, in their nearest approach to each other, causing some slight deviations in their orbits and motions. Some disturbances or inequalities in the motions of Jupiter and Saturn, which could not be accounted for from the mutual action of these planets, led certain astronomers to conclude that another planet of considerable magnitude existed beyond the orbit of Saturn, by the action of which these irregularities were produced. It was not, however, until near the close of the eighteenth century that this happy conjecture was realized and confirmed.—To the late Sir W. Herschel astronomy is indebted for discovering a new primary planet, which had been previously unknown to all astronomers.

This illustrious astronomer, when residing in Bath, had constructed reflecting telescopes of a larger size and with higher powers than any that had been previously in use, and had devoted his unwearied attention to celestial observations.—While pursuing a design which he had formed, of making minute observations on every region of the heavens, on the 13th of March, 1781, while examining, with one of his best telescopes, the constellation of Gemini, he observed a star near the foot of Castor, the light of which appeared to differ considerably from that of the neighboring stars, or those which he found described in catalogues. On applying a higher magnifying power it appeared evidently to increase in diameter; and two days afterward he perceived that its place was changed, and that it had moved a little from its former position. From these circumstances he concluded that it was a comet, and sent an account of it as such to the astronomer royal. As a comet, however, it seemed particularly singular that no tail or nebulous appearance could be perceived; on the contrary, it was found to show with a faint steady light, somewhat paler than that of Jupiter. The account of this discovery soon spread throughout Europe, and was confirmed by observations made at Paris, Vienna, Milan, Pisa, Berlin, and Stockholm. The star was for some time generally considered as an extraordinary comet, free of all nebulosity, and astronomers were occupied in determining the parabolic elements of its course. "The President Bochard de Saron, of the Academy of Sciences of Paris, and Lexel, an astronomer of St. Petersburg, who was in London at the time, were the first who discovered its circular form, and calculated the dimensions of its orbit. It was no longer doubted that Herschel's star was a new planet; and all subsequent observations verified this unexpected result."* We have here a striking proof of the perfection of modern theories; for the laws regulating the motion of this new planet were determined before it had accomplished the twentieth part of its course, and that motion was not less accurately known than that of other planets which had been observed during so many centuries. Since its discovery to the present time, it has not yet moved much more than two-thirds of a revolution round the sun; and yet its motions are calculated, and its place in the heavens predicted, with as much accuracy and certainty as those of the other planets, a circumstance which demonstrates the precision of modern astronomers, and which should lead the unskillful in astronomy to rely on the deductions of this science, however far they may transcend their previous conceptions.

When the motion of this new planet was calculated, the points of the heavens which it successively occupied during the preceding century could be pointed out; and it occurred to some astronomers that it might possibly have been observed before, though not known to be a planet. Mr. Bode, of Berlin, who had just published a work containing all the catalogues of zodiacal stars which had appeared, was induced to consult these catalogues in order to discover whether any star marked by one astronomer, and omitted by another, might not be the new planet in question. In the course of this inquiry he found that the star No. 964 in Mayer's catalogue had been unobserved by others, and observed only once by Mayer himself, so that no motion could have been perceived by him. On this Mr. Bode immediately directed his telescope to that part of the heavens where he might expect to find it, but without success. At the same time he found, by calculation, that its apparent place in the year 1756 ought to have been that of Mayer's star, and this was one of the years in which he was busied in his observations; and, on further inquiry, it was found that the star 964 had been discovered by Mayer on the 15th of September, 1756; so that it is now believed that this star was the new planet of Herschel. It appears likewise that this star was seen several times by Flamstead, the astronomer royal, in the year 1690; once by Bradley; and eleven times by Lemonnier; all of whom considered it as one of the fixed stars, but never suspected that it was a planetary body. The discovery of this planet enlarges our views of the extent of the solar system, and of the quantity of matter it contains, far more than if planets equal to Mercury, Venus, the Earth, the Moon, Mars, Vesta, Juno, Ceres, and Pallas, were to be added to that system; for, although it is scarcely distinguishable by the naked eye on the vault of heaven, it is more than twenty times larger than all these bodies taken together.

---

* Biographical Memoir of Sir W. Herschel, by Baron Fourier. Read to the Royal Academy of Sciences, June 1824.

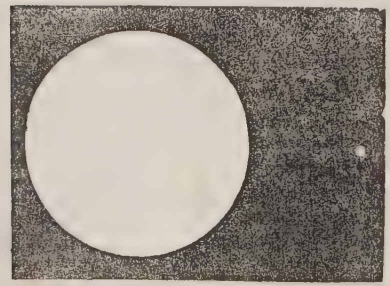
After this body was ascertained to belong to the planetary system, it became a subject of consideration by what name it should be distinguished.—The old planets were distinguished by names borrowed from the heathen deities, a nomenclature which, perhaps, it might now be expedient to change; but Galileo and Cassini gave to the celestial bodies they discovered the names of the princes who had patronized their labors. Hence Galileo, when he had discovered the satellites of Jupiter, sent his drawings of them to his patron, Cosmo Medici, Grand Duke of Tuscany, in honor of whom he called them *Medicean stars;* and Cassini named the satellites of Saturn which he discovered after Louis XIV. In imitation of these discoveries, Sir W. Herschel named his newly-discovered planet *Georgium Sidus,* in honor of his patron George the Third. But foreign astronomers, for a considerable time, gave it the name of *Herschel,* in honor of the discoverer; but afterward hesitated between the names Cybele, Neptune, and *Uranus.* This last name, derived from one of the Nine Muses who presided over astronomy, ultimately prevailed, and will probably distinguish this planet in future generations, unless the present nomenclature of the planets be abolished.

Distance and Period of Uranus.—Uranus is the most distant planet of the solar system, so far as our knowledge yet extends; although it is by no means improbable that planets may exist even beyond its orbit, distant as it is; for comets pass far beyond the limits of this planet, and again return to the vicinity of the sun. Its distance from the sun, in round numbers, is 1,800,000,000; that is, eighteen hundred millions of miles, which is double the distance of the planet Saturn.—When nearest the earth, it is distant from us about 1,705,000,000 of miles. In order to acquire a rude conception of this distance, let us suppose a steam-carriage to set out from the earth, and to move, without intermission, twenty miles every hour, it would require more than nine thousand, seven hundred and thirty years before it could reach the planet Uranus, so that, although the journey had been commenced at the creation of our globe, it would still require more than three thousand seven hundred years to arrive at its termination. Even a cannon ball, flying at the rate of twelve thousand miles every day, would require three hundred and eighty-nine years to reach the nearest point of the orbit of this planet. Yet the comet which appeared in 1835, in all probability, pursues its course far beyond the orbit of Uranus, and will, doubtless, visit this part of our system again, as it has done before, within the space of seventy-six years, although it must move more than double the above distance before it returns. The *circumference* of the orbit in which Uranus revolves about the sun is 11,314,000,000 of miles, through which it moves in 30,686 mean solar days, or about eighty-four years. It is the slowest moving planet in the system, and yet it pursues its course at the rate of 15,000 miles every hour.—Were a steam-carriage to move around the immense orbit of this planet at the rate above stated, it would require no less than sixty-four thousand, five hundred and seventy years before this ample circuit could be completed; and yet a globe eighty times larger than the earth finishes this vast tour in eighty-four years! This planet doubtless revolves round its axis as the other planets do, but the period of its rotation is as yet unknown. Its great distance from the earth prevents us from observing any spots or changes on its surface by which its rotation might be determined. La Place concludes, from physical considerations, that it revolves about an axis very little inclined to the ecliptic; and that the time of its diurnal rotation cannot be much less than that of Jupiter or Saturn.

Magnitude and Dimensions of Uranus.—This planet is about 35,000 miles in diameter, and 110,000 miles in circumference, being about eighty-one times larger than the earth, and four thousand times larger than the moon. Its surface contains 3,848,460,000 of square miles, which is 19 times the area of our globe, and 78 times the area of all the habitable portions of the earth. At the rate of population formerly stated, 280 to a square mile, it could, therefore, accommodate 1,077,568,800,000, or more than one billion of inhabitants, which is one thousand three hundred and forty-seven times the population of our globe. So that this planet, which escaped the notice of astronomers for more than five thousand years, forms a very considerable portion of the solar system and of the scene of the Divine government

Proportion of Light on Uranus.—As this planet is nineteen times farther from the sun than the earth is, and as the square of 19 is 361, the intensity of light on its surface will be three hundred and sixty times *less* than what we enjoy. Yet this quantity of light is equal to what we should have from the combined effulgence of three hundred and forty-eight full moons; and, with a slight modification of our visual organs, such a proportion of light would be quite sufficient for all the purposes of vision. Though the light of the sun flies eighteen hundred millions of miles before it reaches this planet, and returns again by reflection nearly the same distance before it reaches the earth, yet it is distinctly visible through our telescopes, and sometimes even to the naked eye; and Uranus, with a moderate magnifying power, *appears* about as bright as Saturn. How small a quantity of solar light may suffice for the purpose of vision will be obvious by attending to the following circumstance: In the late solar eclipse which happened on the 15th of May, 1836, little more than the one-twelfth part of the sun was visible at those places where the eclipse was annular. Almost every person imagined that a dismal gloom and darkness would ensue, yet the diminution of light appeared no greater than what frequently happens in a cloudy day. At the time of the greatest obscuration there was more than half the light which falls upon Uranus, and all the objects of the surrounding landscape, though somewhat deficient in brilliancy, were distinctly perceived. There can be no doubt that the organs of vision of the inhabitants of the different planets, being formed by Divine wisdom, are exactly adapted to the objects amid which they are placed, and the quantity of light reflected from them; and there may be innumerable modes, unknown to us, by which this end may be effected. We can easily conceive, that if the pupils of our eyes were rendered capable of a greater degree of expansion than they now possess, or were the *retina*, on which the images of objects are depicted, endowed with a greater degree of nervous sensibility, so as to be more easily affected by the impulses of light, we might perceive as much splendor on all the objects connected with Uranus, were we placed on that planet, as we now do on the scenery around us during the brightest days of summer. When we pass from the light of the sun into a darksome apartment, on our first entrance we can scarcely distinguish any objects with distinctness; but after remaining five or six minutes, until the pupil has time to expand, every object around us is readily perceived; and, from the same cause, nocturnal animals can pursue their course with ease and certainty amid the deepest shades of night; so that the inhabitants of the most distant planet of our system, although it were removed from the sun to double the distance of Uranus, might perceive objects with all the distinctness requisite for the purposes of vision; and if the pupils of the eyes of such beings be much more expansive than ours (as is probably the case), it is highly probable they will be enabled to penetrate much farther into the celestial regions, and to perceive the objects in the firmament with much greater distinctness and "space-penetrating power" than we can do, even with the aid of instruments. It is likewise probable that the objects on the surface of the more distant planets of our system are fitted to reflect the rays of light with peculiar brilliancy. Hence we find that the light of Uranus, though descending upon us from a region 900 millions of miles farther than Saturn, appears as vivid as the light which is reflected to us from that planet. The apparent diameter of the sun, as seen from Uranus, is only 1 minute, 38 seconds; whereas his mean apparent diameter as seen from the earth is 32 minutes, 3 seconds; consequently this orb, as viewed from this planet, will appear very little larger than Venus appears to us in her greatest brilliancy, or Jupiter when near his opposition. The foregoing figure represents to the eye the apparent size of the sun as seen from Uranus and from the earth, the small circle representing his size as seen from Uranus.

Fig. 66.



Temperature of Uranus.—If heat followed the same law as the propagation of light, and decreased as the square of the distance of the planet from the sun increased, then the surface of the planet Uranus would be a cold region indeed, in which no life or animation, such as we see around us, could exist. Baron Fourier, in his "Memoir of Herschel," says, "Its temperature is more than forty degrees below that of ice;" and if the degrees of Reaumur's thermometer be meant, this temperature will correspond to one hundred and twenty-two degrees below the freezing point of Fahrenheit; a cold enough region, truly. In accordance with such representations, the poets of the last century expatiated on the cold temperature of *Saturn* in such strains as the following:

> "When the keen north with all its fury blows,
> Congeals the floods, and forms the fleecy snows,
> 'T is heat intense to what can there be known;
> Warmer our poles than is its burning zone.
> Who there inhabit must have other powers,
> Juices, and veins, and sense, and life, than ours.
> One moment's cold, like theirs, would pierce the bone,
> Freeze the heart's blood, and turn us all to stone."
> BAKER'S *Universe.*

This, it must be admitted is *a very cold* poetic strain, almost sufficient to make one shiver, and to freeze our very thoughts; and if such a description were applicable to Saturn, it is much more so to the planet Uranus, at double the distance.—But I presume it is more in accordance with poetic license than with the deductions of sound philosophy. We have no valid reason to conclude that the degree of heat on the surfaces of the different planets is inversely proportional to the squares of their respective distances from the sun. The sun is to be considered chiefly as the great storehouse of *light*, and it may likewise be viewed as the great agent in the production of heat, without supposing it to be an enormous mass of fire, which the common opinion seems to take for granted. Its rays produce heat chiefly by exciting an insensible action between *caloric* and the particles of matter contained in bodies; and caloric appears to be a substance universally diffused throughout nature. If the degree of heat were in proportion to the distance from the sun, why should the upper regions of the atmosphere be so intensely cold? Why should the tops of lofty mountains be crowned with perpetual snows, while the plains below are scorched with heat?—Why should an intense cold be felt in the latitude 40°, when a comparative mildness is experienced in the latitude of 56°? In the state of Connecticut, North America, in January, 1835, the thermometer ranged from *minus* 25° to 27° of Fahrenheit; while in Scotland, during the same period, it was seldom so low as the freezing point.—But as I have already thrown out some remarks on this subject when describing the planet Mercury, I need not enlarge (see page 28). In order to form correct ideas of the distribution of heat among the planetary bodies, we have only to suppose that the Creator has proportioned the quantity of caloric (or that which produces sensible heat) to the distance at which every planet is placed from the sun, so that a large quantity exists in Saturn and a smaller quantity in Mercury. If, therefore, the quantity of caloric connected with Uranus be in proportion to its distance from the sun, there may be as much warmth experienced in that distant region of the solar system as in the mildest parts of our temperate zones. So that we are under no necessity of associating the frigid and gloomy ideas of the poet with our contemplations of this expansive globe. At all events, we may rest assured that the Creator, whose wisdom is infinite in its resources, and whose "tender mercies are over all his works," has adapted the structure and constitution of the inhabitants of every planet to the nature and circumstances of the habitation provided for them, so as to render every portion of his dominions a comfortable abode for his intelligent offspring; provided they do not frustrate his benevolent designs (as has been done in our world) by their rebellion and immoral conduct. For in no region of the universe, whatever may be its physical arrangements, can true happiness be enjoyed, unless love to God and love to all surrounding intelligences form the grand principles of action, and be uniformly displayed in every intercourse and association, and amid all the ramifications of moral conduct. On this basis chiefly rests the happiness of the intelligent universe; and, wherever principles directly opposite to these prevail among any order of intellectual beings, whatever may be the structure or scenery of their habitation, misery and moral disorder must be the inevitable consequence.

The following additional particulars may be stated in relation to this planet: Its *density* is reckoned to be nearly equal to that of water. A body weighing one pound on the earth's surface would weigh only fourteen ounces, fourteen drachms, if removed to Uranus. The *eccentricity* of its orbit is 85,000,000 of miles, which is about the 1-42d part of its diameter. Its mean *apparent diameter*, as seen from the earth, is about four seconds. The *inclination of its orbit* to the ecliptic is forty-six minutes, twenty-six seconds, so that it is never much more than three-fourths of a degree from the ecliptic. This inclination is less than that of any of the other planetary orbits. Six satellites are supposed to be connected with Uranus, but their periods and other phenomena have not yet been accurately ascertained.

In the preceding pages I have given a brief sketch of the principal phenomena connected with the *primary* planets of our system. Whether any other planets beside those specified belong to this system is at present unknown. We have no reason to believe that the boundaries of the planetary system are circumscribed within the range of our discoveries or the limits of our vision. Within the space of little more than half a century, the limits of this system have been expanded to our view to double the extent which they were formerly supposed to comprehend. Instead of an area of only 25,400,000,000 of square miles, it is now found to comprise an extent of 101,700,000,000 of square miles, which is four times the dimensions formerly assigned to it. There would be no improbability in conceiving it extended to at least triple these dimensions. Within the space of twenty-six years, from 1781 to 1807, no fewer than five primary planets and eight secondaries were discovered, beside a far greater number of comets than had ever before been detected within a similar lapse of years; and therefore it would be obviously rash and premature to conclude that we have now discovered all the moving bodies of our system. Far beyond the limits of even Uranus other planets yet unknown may be performing their more ample circuits around the sun; for we know, from the case of comets, that even throughout those distant regions his attractive power and influence extend. In the immense interval of 900,000,000 of miles between the orbits of Saturn and Uranus, one, if not two planets may possibly exist, though they have hitherto eluded the observation of astronomers. In order to detect such bodies, if any exist, it would be requisite to survey, more minutely than has yet been done, a zone of the heavens extending at least twenty degrees on each side of the ecliptic, marking exactly the minutest objects in every part of it which the most powerful telescopes can enable us to descry. After which a second survey should be made to ascertain if any of the bodies formerly observed be found missing or have shifted their position. It might likewise be expedient to compare with new observations the stars marked in all the celestial atlases that have hitherto been published, and to note particularly those which are wanting where they were formerly marked, and those that have appeared in certain places where they were formerly unobserved. If a taste for celestial investigations were more common among mankind, and were the number of observers indefinitely increased, there would be no great difficulty in accomplishing such an object; for certain small portions of the heavens might be allotted to different classes of observers, who might proceed simultaneously in their researches, and in a comparatively short period the whole survey might be completed.

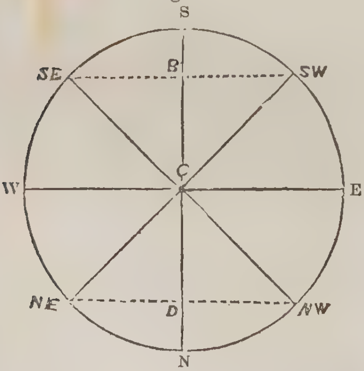
It is not improbable that a planet may exist within the space of 37 millions of miles which intervenes between the orbit of Mercury and the sun. But such a body could never be detected in the evening after sunset, as its greatest elongation from the sun could not be supposed to be more than ten or twelve degrees, and, consequently, it would descend below the horizon in about half an hour after sunset, and before twilight had disappeared. The only chance of detecting such a planet would be when it happened to transit the sun's disc; but as this would happen only at distant intervals, and as it might make the transit in cloudy weather, or when the sun is absent from our hemisphere, there is little prospect of our discovering such a body in this way. It might be of some importance, however, that those who make frequent observations on the sun should direct their attention to this circumstance; as there have been some instances in which dark bodies have been observed to move across the sun's disc in the space of five or six hours, when no other spots were visible. An opaque body of this description was seen by Mr. Lloft and others on the 6th of January, 1818, which moved with greater rapidity across the solar disc than Venus in her transit in 1769. It is possible that a planet within the orbit of Mercury might be detected in the day-time, were powerful telescopes applied to a space of the heavens about ten or twelve degrees around the sun. Small stars have been seen even at noonday with powerful instruments, and, consequently, a planet even smaller than Mercury might be perceived in the day-time. In this case, a round opaque body would require to be placed at a considerable distance from the observer, so as completely to intercept the body of the sun, and about a degree of the heavens all around him; and every portion of the surrounding space, extending to at least twelve degrees in every direction, should then be carefully and frequently examined. Such observations, if persevered in, would undoubtedly afford a chance of detecting any revolving body that might exist within such a limit. But I may afterward have an opportunity of describing more particularly the observations, and the mode of conducting them, to which I allude.

X. THE SUN.

Having taken a cursory survey of the most prominent particulars connected with the primary planets, I shall now proceed to a brief description of the *sun*, that magnificent luminary on which they all depend, from which they derive light, and heat, and vivifying influence, and by whose attractive energy they are directed in their motions and retained in their orbits. Before proceeding to a description of the particular phenomena connected with the sun, it may be expedient briefly to describe some of his *apparent* motions.

Apparent Motions of the Sun.—The most obvious apparent motion of the sun, which is known to every one, is, that he appears to rise in the morning in an easterly direction, to traverse a certain portion of the sky, and then to disappear in the evening in a direction toward the west. Were we to commence our observations on the 21st of December, in the latitude of 52° north, which nearly corresponds to that of London, we should see the sun rising near the south-east point of the horizon, as at *S E*, Fig. 67, describing a comparatively small curve above the horizon, from *S E* to *S W*, in the southern quarter of the heavens, and setting at *S W*, near the south-west. At this season the sun remains only between seven and eight hours above the horizon; and when he arrives at *S*, at midday, which is the highest point of his elevation, he is only about fourteen degrees above the horizon, which may be represented by the line *S B*. After disappearing in our horizon in the evening, he describes the large curve from *S W* to *W*, *N*, and *E*, until he again arrives in the morning near the point *S E*. All this curve is described *below* our horizon, and, therefore, the nights at this season are much longer than the days. After this period the sun rises every day at points a little farther to the north, between *S E* and *E*, and sets in corresponding points in the west, between *S W* and *W*, until the 21st of March, when he rises at the point *E*, due east, and sets due west at the point *W*. At this time he moves through the semicircle *E, S, W*, and at noon he rises to the elevation of thirty-eight degrees above the southern horizon, which may be represented by the line *S C*. This is the period of the vernal equinox, when there is equal day and night throughout every part of the earth, the sun being twelve hours above and twelve hours below the horizon. After this period the sun rises to the north of the easterly point, and sets to the north of the westerly, and the length of the day rapidly advances until the 21st of June, when he rises near the north-east point, *N E*, and sets near the north-west point, *N W*, describing the large curve from *N E* to *E S W*, and *N W*. This period of the year is called the summer *solstice*, when the days are longest, at which time the sun rises at noon to an elevation of 61½ degrees above the horizon, which may be represented by the line *S D*, and he continues above the horizon for nearly seventeen hours. The length of the nights at this time is exactly the same as the length of the days on the 21st of December. The sun's nocturnal arch, or the curve he describes below the horizon, is that which is represented in the lower part of the figure from *N W* to *N E*. In more southern latitudes than fifty-two degrees, the sun rises to a higher elevation at noon; and in higher latitudes his meridian altitude is less than what is stated above. From the time of the summer solstice the days gradually shorten; the sun rises in a more southerly direction until the 23d of September, which is called the *autumnal equinox*, when he again rises in the eastern point of the compass, and every succeeding day at a point still farther to the south, until, on the 21st of December, or the *winter solstice*, he is again seen to rise near the south-east, and afterward to pass through all the apparent variations of motion above described.

Fig. 67.



Were we residing in southern latitudes, such as those of Buenos Ayres, the Cape of Good Hope, or Van Dieman's Land, the apparent motions of the sun would be somewhat different. Instead of beholding the sun moving along the *southern* part of the sky from the left hand to the right, we should see him direct his course along the northern part of the heavens from the right hand to the left. In other respects his apparent motions would nearly correspond to those above described. Were we placed in countries under the equator at the time of the equinoxes, the sun at midday would shine directly from the zenith, at which time objects would have no shadows. At all other times the sun is either in the northern or the southern quarter of the heavens. During the one-half of the year he shines from the north, and the shadows of objects fall to the south; during the other half he shines from the south, and the shadows of all objects are projected toward the north. This is a circumstance which can never occur in our climate or in any part of the temperate zones. At the equator, too, the days and nights are of the same length, twelve hours each, throughout the whole year. Were we placed at the *poles*, the motion of the sun would present a different aspect from any of those we have described. At the north pole, on the 21st of March, we should see a portion of the sun's disc appear in the horizon after a long night of six months. This portion of the sun would appear to move quite round the horizon every twenty-four hours; it would gradually rise higher and higher until the whole body of the sun made its appearance. As the season advanced, the sun would appear to rise higher and higher until he attained the altitude of 23½ degrees above the horizon, which would take place on the 21st of June; after which his altitude would gradually decline until the 23d of September, when he would again appear in the horizon. During the whole of this period of six months there is perpetual day, the stars are never seen, and the sun appears to go quite round the heavens every twenty-four hours without setting, in circles nearly parallel to the horizon. After the 23d of September the sun disappears, and a night of six months succeeds, which is occasionally enlivened by the moon, the stars, and the coruscations of the *aurora borealis*, during which period the south pole enjoys all the splendor of an uninterrupted day. In all places within the polar circles, the length of the longest day varies from twenty-four hours to six months. In the northern parts of Lapland, for example, the longest day is about six weeks; during this time the sun appears to move round the heavens without setting; but at noon, when he comes to the meridian, he is about 40 degrees above the *southern* horizon, and twelve hours afterward he appears elevated about six degrees above the *northern* horizon, from which point he again ascends until he arrives at the southern meridian.

Such are the apparent *diurnal* motions and general aspects of the sun in different parts of the earth, which are owing partly to the inclination of the axis of the earth to the plane of the ecliptic, and partly to the different positions in which a spectator is placed in different zones of the globe. It is almost needless to remark, that these motions of the sun are not *real*, but only *apparent*. While presenting all these varieties of motion, he is still a quiescent body in the center of the planetary system. By the rotation of the earth round its axis, from west to east, every twenty-four hours, all these apparent motions of the sun are produced. This we have already endeavored to prove in chap. i, pp. 16–17.

Beside the apparent diurnal motion now described, there is another apparent motion of the sun in a contrary direction, which is not so much observed, and that is, his apparent motion from *west* to *east* through the whole circle of the heavens, which he accomplishes in the course of a year. This motion manifests itself by the appearance of the heavens during the night. The stars which lie near the path of the sun, and which set a little time after him are soon lost in his light, and after a short time reappear in the east a little before his rising. This proves that the sun advances toward them in a direction contrary to his diurnal motion; and hence we behold a different set of stars in our nocturnal sky in summer and in winter. This apparent revolution of the sun is produced by the *annual* motion of the earth round the sun, of which I have already given an explanation (chap. i, p. 17,) along with certain demonstrative proofs that the sun is the center of the planetary system (see also chap. ii, pp. 22–26).

Distance and Magnitude of the Sun.—To find the exact distance of the sun from the earth is an object which has much interested and engaged astronomers for a century past. The angle of parallax being so small as about eight and a half seconds, rendered it for some time difficult to arrive at an accurate determination on this point, until the transits of Venus in 1761 and 1769. From the calculations founded upon the observations made on these transits, it has been deduced that the distance of the sun is about 95,000,000 of miles. This distance is considered by La Place and other astronomers to be within the 1-87th part of the true distance, so that it cannot be much below 94 millions on the one hand, nor much above 96 millions on the other. Small as this interval may appear when compared with the vast distances of some of the other celestial bodies, it is, in reality, a most amazing distance when compared with the spaces which intervene between terrestrial objects; a distance which the mind cannot appreciate without a laborious effort. It is thirty-one thousand six hundred times the space which intervenes between Britain and America; and were a carriage to move along this space at the rate of 480 miles every day, it would require 542 years before the journey could be accomplished.

The *magnitude* of this vast luminary is an object which overpowers the imagination. Its diameter is 880,000 miles; its circumference, 2,764,600 miles; its surface contains 2,432,800,000,000 of square miles, which is twelve thousand three hundred and fifty times the area of the terraqueous globe, and nearly fifty thousand times the extent of all the habitable parts of the earth. Its solid contents comprehend 356,818,739,200,000,000,* or more than three hundred and fifty-six thousand billions of cubical miles. Were its center placed over the earth, it would fill the whole orbit of the moon, and reach 200,000 miles beyond it on every hand. Were a person to travel along the surface of the sun, so as to pass along every square mile on its surface, at the rate of thirty miles every day, it would require more than two hundred and twenty millions of years before the survey of this vast globe could be completed. It would contain within its circumference more than thirteen hundred thousand globes as large as the earth, and a thousand globes of the size of Jupiter, which is the largest planet of the system. It is more than five hundred times larger than all the planets, satellites, and comets belonging to our system, vast and extensive as some of them are. Although its density is little more than that of water, it would weigh 3360 planets such as Saturn, 1067 planets such as Jupiter, 329,000 globes such as the earth, and more than *two millions* of globes such as Mercury, although its density is nearly equal to that of lead. Were we to conceive of its surface being peopled with inhabitants at the rate formerly stated, it would contain 681,184,000,000,000, or more than six hundred and eighty billions, which would be equal to the inhabitants of *eight hundred and fifty thousand worlds* such as ours.

Of a globe so vast in its dimensions, the human mind, with all its efforts, can form no adequate conception. If it is impossible for the mind to take in the whole range of the terraqueous globe, and to form a comprehensive idea of its amplitude and its innumerable objects, how can we ever form a conception, approaching to the reality, of a body one million three hundred thousand times greater? We may express its dimensions in figures or in words, but in the present state of our limited powers we can form no mental image or representation of an object so stupendous and sublime. Chained down to our terrestrial mansion, we are deprived of a sufficient range of prospect, so as to form a substratum to our thoughts, when we attempt to form conceptions of such amazing magnitudes. The imagination is overpowered and bewildered in its boldest efforts, and drops its wings before it has realized the ten thousandth part of the idea which it attempted to grasp. It is not improbable that the largest ideas we have yet acquired or can represent to our minds of the immensity of the universe are inferior to a *full and comprehensive idea* of the vast globe of the sun in all its connections and dimensions; and, therefore, not only must the powers of the human mind be invigorated and expanded, but also the limits of our intellectual and corporeal vision must be indefinitely extended, before we can grasp the objects of overpowering grandeur which exist within the range of creation, and take an enlightened and comprehensive view of the great Creator's empire. And as such endowments cannot be attained in the present state, this very circumstance forms a presumptive argument that man is destined to an immortal existence, where his faculties will be enlarged and the boundaries of his vision extended, so as to enable him to take a large and comprehensive view of the wonders of the universe, and the range of the Divine government. In the meantime, however, it may be useful to allow our thoughts to expatiate on such objects, and to endeavor to form as comprehensive an idea as possible of such a stupendous luminary as the sun, in order to assist us in forming conceptions of objects still more grand and magnificent; for the sun which enlightens our day is but one out of countless millions of similar globes dispersed throughout creation, some of which may far excel it in magnitude and glory.

---

* In some editions of the "Christian Philosopher," under the article *Astronomy*, this number is inaccurately stated; and the number which follows, *two thousand millions*, should be *two hundred millions.*

Rotation of the Sun.—This luminary, although it is placed in the center of the system, in the enjoyment of perpetual day, and stands in no need of light from any other orb, yet is found to have a rotation round its axis. This circumstance seems to indicate that motion is essential to all the bodies of the universe, whether revolving in orbits around another body, or acting as the centers of light and attractive influence. And from what we know of the more distant bodies in the heavens, we have reason to believe that there is none of them in a state of absolute quiescence, but that they are all in incessant motion, either round their axes, or around a distant center. The rotation of the sun was discovered by the motion of certain dark spots across its disc. These spots appear to enter the disc on the east side, to move from thence with a velocity continually increasing until they arrive at the middle of the disc; they then move slower and slower until they go off at the sun's western limb; after which they disappear for about the same space of time they occupied in crossing the disc, and then enter again on the eastern limb and move onward in the same track as before, unless they suffer a change, as frequently happens, after they disappear from the western limb. The apparent *inequality* in the motion of the spots is purely optical, and is owing to the oblique view we have of the parts of a globe which are near the margin; but the motion is such as demonstrates that the spots are carried round with a uniform and equable motion.—From the motion of these spots we learn, 1. That the sun is a globe, and not a flat surface; 2. That it has a rotation round its own axis; and, 3. That this rotation is performed in the same direction as the rotation of the planets and their annual revolutions, namely, according to the order of the signs of the zodiac. The time which a spot takes in moving from the eastern to the western limb is thirteen days and nearly sixteen hours, and, consequently, the whole apparent revolution is twenty-seven days and nearly eight hours. But this is not the true period of the sun's rotation; for as the earth has, during this time, advanced in its orbit from east to west, and in some measure followed the motion of the spot, the real time in which the spots perform their revolutions is found, by calculation,* to be twenty-five days, ten hours. Every part of the sun's equator, therefore, moves at the rate of 4532 miles every hour. The axis of the sun, round which this revolution is performed, is inclined 7 degrees 20 minutes to the ecliptic.

The Solar Spots, and the Physical Construction of the Sun.—Although the sun is the fountain of light, and is incessantly pouring a flood of radiance over surrounding worlds, yet the nature of this vast luminary, and the operations which are going on upon its surface and adjacent regions, are in a great measure involved in darkness.—Before stating any opinions on this subject, it may be proper, in the first place, to give a brief description of the phenomena which have been observed on the surface of the sun. The first and most striking phenomenon is the dark spots to which we have alluded. These spots are of all sizes, from one twenty-fifth part of the sun's diameter to the one five-hundreth part and under. The larger spots are uniformly dark in the center, and surrounded with a kind of border or fainter shade, called a *penumbra.* This penumbra, which sometimes occupies a considerable space around the dark nucleus, is frequently of a shape nearly corresponding to that of the black spot. Sometimes two or more dark spots, and a number of small ones are included within the same *penumbra*, and at other times a number of small spots in a train, forming a kind of tail, accompany the larger ones. The *number* of the spots is very various; sometimes there are only two or three, sometimes above a hundred, and sometimes none at all. *Scheiner*, who was among the first that observed these spots, remarks, that "from the year 1611 to 1629 he never found the sun quite clear of spots, except a few days in December, 1624; at other times he was able to count twenty, thirty, and even fifty spots upon the sun at a time." Afterward, during an interval of twenty years, from 1650 to 1670, it is said that scarcely any were to be seen. But, since the beginning of last century, no year has passed, so far as we know, in which spots have not been seen. I have had an opportunity of viewing the sun with good telescopes several hundreds of times, but have seldom seen his surface altogether free of spots.—In some years, however, they have been far more numerous than in others. In the beginning of 1835 comparatively few were seen, but during the latter part of it, the whole of 1836, and up to the present time (September, 1837), they have been exceedingly numerous. On the 16th of November, 1835, with an achromatic telescope, magnifying about a hundred times, I perceived about ten different clusters; and, within the limits of two of the clusters, sixty different spots were counted, and in the whole of the other clusters above sixty more; making in all about 120 spots, great and small. On the 19th of October, 1836, and the 21st of February, 1837, I counted about 130; and on a late occasion I perceived spots of all descriptions to the amount of about 150. Such a number of spots are generally arranged into ten or twelve different clusters, each cluster having one or two large spots, surrounded with a number of smaller ones. Fig. 68, represents the spots of the sun nearly as they appeared on the 19th of October, 1836, some of the smaller

---

*The following is the proportion by which the true rotation is found: 365*d.* 5*h.* 48*m.* + 27*d.* 7*h.* 37*m.*; or, 392*d.* 13*h.* 25*m.* 365*d.* 5*h.* 48*m.* : : 27*d.* 7*h.* 37*m.*: 25*d.* 9*h.* 56*m.* = the true time of the sun's rotation.

spots being omitted. The larger spots are represented on a somewhat larger scale than they should be in proportion to the diameter of the circle; but they present nearly the same relative aspect they exhibited when viewed through the telescope at the time specified. Fig. 69 shows the large spot on a larger scale; and Fig. 70 a large spot which appeared in a subsequent observation, which had a bright streak or two in the center.

The magnitude of some of the solar spots is astonishing. One of the spots seen November 16, 1835, was found to measure about the *fortieth part* of the sun's diameter; and as that diameter is equal to 880,000 miles, the diameter of the spot must have been 22,000 miles, which is nearly three times the diameter of the earth; and if we suppose it only a flat surface, and nearly circular, it contained 380,133,600 square miles, which is nearly double the area of our globe. The largest of the spots in the figure, including the penumbra, measured about the one twenty-first part of the sun's diameter; and its breadth about the 1-54th part of the same diameter; consequently the length of the spots and penumbra was 41,900 miles, its breadth 16,300, and its area 6,829,700,000 square miles, which would afford room for ten globes as large as the earth to be placed upon it. It consisted of a dark spot of a longish form, about 12,000 miles in length, and two or three smaller spots, some of them several thousand miles long, all included within one penumbra. The smallest spots we can discern on the solar disc cannot be much less than five or six hundred miles in diameter.

These spots *are subject to numerous changes*. When watched from day to day, they appear to enlarge or contract, to change their forms, and at length to disappear altogether, or to break out on parts of the solar surface where there were none before. Hevelius observed one which arose and vanished in the space of seventeen hours. No spot has been known to last longer than one that appeared in the year 1676, which continued upon the sun above seventy days; but it is seldom that any spots last longer than six weeks. Those spots that are formed gradually are generally gradually dissolved; those which arise suddenly are, for the most part, suddenly dissolved. Dr. Long, in his "Astronomy," vol. ii, states, that "while he was viewing the image of the sun cast through a telescope upon white paper, he saw one roundish spot, by estimation not much less in diameter than our earth, break into two, which immediately receded from one another with a prodigious velocity." The Rev. Dr. Wollaston, when viewing the sun with a reflective telescope, perceived a similar phenomenon. A spot burst in pieces while he was observing it like a piece of ice, which, thrown upon a frozen pond, breaks in pieces and slides in various directions. On the 11th of October, 1833, at 2h. 30′ P. M., I observed a large spot, with several smaller ones behind it, as represented Fig. 71. Next day, at 0h. 30′ P. M., the small spots marked *e* had entirely disappeared, and no trace of them was afterward seen. Each of these spots was more than a thousand miles in diameter, yet they were all changed in the space of twenty-two hours. The spot marked *d*, near the large spot, though at least two or three thousand miles in length, disappeared about three days afterward. When any spot begins to increase or diminish, the nucleus, or dark part, and the penumbra contract and expand at the same time. During the process of diminution, the penumbra encroaches gradually upon the nucleus, so that the figure of the nucleus and the boundary between it and the penumbra are in a state of perpetual change; and it sometimes happens during these variations, that the encroachment of the penumbra divides the nucleus into two or more parts. These circumstances show that there is a certain connection between the penumbra and the nucleus; yet it is observed, that when the spots disappear the penumbra continues for a short time visible after the nucleus has vanished. It is likewise observed that the exterior boundary of the penumbra never consists of sharp angles, but is always curvilinear, how irregular soever the outline of the nucleus may be. The portions of the sun on which spots of any description are perceived lie from thirty to fifty degrees on each side of its equator. No spots are ever seen about its polar regions, though I have sometimes seen small spots as distant from the equator as sixty degrees.

76

Fig. 72 shows the progress of a spot across the sun's disc, from its eastern to its western limb, as observed and delineated by Hevelius, in May, 1644. The figures refer to the number of days on which the spot was observed. On the first day of the observation, when the spot first appeared on the eastern limb, it was seen as represented at 1; the second day it was not visible, by reason of cloudy weather. The third, fourth, and fifth days it gradually increased in bulk; the sixth day it was not seen. On the tenth and following days the spot was vastly increased in bulk, with an irregular atmosphere about it and a dark central spot. Figs. 73, 74, 75, 76, are representations of spots by Sir W. Herschel. Fig. 75 shows the division of a decaying nucleus or opening, where the luminous passage across the opening resembles a bridge thrown over a hollow.

Beside the dark spots now described, there are other spots which have a bright and mottled appearance, which were formerly termed *faculæ*, and which Sir W. Herschel distinguished by the terms *Nodules, Corrugations*, and *Ridges*. These spots are chiefly to be seen near the margin of the sun, in the same latitudes in which the other spots appear. They appear first on the eastern margin, and continue visible for three or four days, but are invisible when they arrive near the middle of the disc, and when they approach near the western limb they are again distinctly visible. This circumstance shows that they are ridges or elevations, which appear in profile when near the limb, but in front or foreshortened when near the middle of the disc, so as to become invisible.—They are generally seen in the immediate neighborhood of dark spots, and in the places where spots have appeared; and hence, for several years past, when any of these faculæ or ridges have appeared on the eastern margin, I have uniformly been enabled to predict the appearance of a large spot or two within the course of twenty-four or thirty hours; and in more than twenty or thirty instances I have never been disappointed. These faculæ and ridges present a mottled and waving appearance, like that of a country with gentle elevations and depressions, and bear a strong resemblance to certain portions of that surface of the moon, particularly the more level portions of the orb, which present a number of gentle wavings or elevations and depressions. And as those wavings or ridges which appear on the sun are, in a clear atmosphere, as distinctly perceptible as the rough surface of the moon, they must be objects of immense extent and of very great elevation, whether they consist of luminous clouds or of more dense materials. Some of those spaces or ridges have been found to occupy a portion of the solar disc equal to seventy-five thousand miles. They extend over a large portion of the sun's surface, and their shape and position are frequently changing.

Opinions and Deductions respecting the Nature and Constitution of the Sun.—Having described the principal phenomena connected with this immense luminary, we may now consider what conclusions those appearances lead us to deduce respecting its construction and the processes which are going on near its surface. Very vague and foolish opinions have been entertained respecting the nature of the sun ever since the invention of the telescope. It has very generally been considered as a vast body of liquid fire; and in a large volume now before me, published only about a century ago, it is considered as the local place of *hell*. A large map of the sun, copied from the delineations of *Kircher* and *Scheiner*, is exhibited, in which the solar surface is represented as all over covered with flames, smoke, volcanoes, and "great fountains, or ebullitions of fire and light, spread thick over the whole body of it; and in many places *dark spots*, representing dens or caverns, which may be supposed the seats of the blackness of darkness."[*] In this picture the smoke and flames are represented as rising beyond the margin of the sun about a ninth part of its diameter, or nearly 90,000 miles; a picture as unlike the real surface of the sun as the gloom of midnight is unlike the splendors of day. But, leaving such extravagant and untenable notions, even some philosophers have held opinions altogether incompatible with reason and with the phenomena presented by the sun: Galileo, Hevelius, and Maupertius considered the spots as *scoria* floating in the inflammable liquid matter of which they conceived the sun to be composed. Others have imagined that the fluid which sends forth light and heat contains a nucleus or solid globe, in which are several volcanoes, like Etna or Vesuvius, which from time to time cast forth quantities of bituminous matter up to the surface of the sun, and form those spots which are seen upon it; and that, as this matter is gradually changed and consumed by the luminous fluid, the spots disappear for a time, but are seen to rise again in the same places when those volcanoes cast up new matter. Others, again, have supposed that the sun is a fiery luminous fluid, in which several opaque bodies of irregular shapes are immersed, and that these bodies are sometimes buoyed up or raised to the surface, where they appear like spots; while others imagine that this luminary consists of a fluid in continual agitation, by the rapid motion of which some parts more gross than the rest are carried up to the surface in like manner as scum rises on the top of melted metal or anything that is boiling. The futility of all such opinions is obvious when we consider attentively all the varieties of the solar phenomena, and when we reflect on the immense magnitude both of the sun itself and of the spots which traverse its surface. What resemblance can there be between such volcanoes as Etna and Vesuvius, and spots on the sun 20,000 miles in diameter, and several times larger than the whole earth? between the vast and sublime operations going forward in this magnificent globe, and "the *scum* and *scoria* of melted metal?" We err most egregiously when we attempt to compare the substances and the puny operations which we see around us on the globe we inhabit, with what takes place on so stupendous a globe as the sun, whose constitution must be so immensely different from that of the planetary bodies, and from everything within the range of our observation on this earth. We talk of volcanoes, of scoria, of boiling metals, of bituminous matter, of dens, and caverns, and fiery flames in the sun, as if they were as common there as with us; whereas there is every reason to believe that nothing similar to any of these is to be found in the constitution of this vast luminary. We might, with as good reason, attempt to compare the process of vegetation on our globe, and the tides and currents of our ocean, with what takes place on the surface of Jupiter or on the rings of Saturn. In all such cases, it is most becoming rather to acknowledge our ignorance than to caricature and degrade the sublimest works of Omnipotence by our puerile explanations and whimsical theories. The following are some of the more rational conclusions which have been deduced in reference to the constitution of the sun.

---

[*] "An Inquiry into the Nature and Place of Hell." By the Rev. T. Swinden, M. A., Rector of Cuxton, in Kent, 2d edit., p. 470. London, 1727.

In the first place, from a variety of observations, it is now pretty well determined that the solar spots are *depressions*, and not elevations, and that the black nucleus of every spot is the opaque body of the sun seen through an opening in the luminous atmosphere with which it is environed. This was first ascertained by numerous observations made by the late Dr. Wilson, professor of astronomy in the university of Glasgow. This conclusion is founded on the following facts: When any spot is about to disappear behind the sun's western limb, the eastern portion of the umbra first contracts in its breadth, and then vanishes. The nucleus then contracts and vanishes, while the western portion of the umbra still remains visible. When a spot comes into view on the sun's eastern limb, the eastern portion of the umbra first becomes visible, then the dark nucleus, and then the western part of the umbra makes its appearance. When two spots are near each other, the umbra of the one spot is deficient on the side next the other; and when one of the spots is much larger than the other, the union of the largest will be completely wanting on the side next the small one. From various micrometrical estimates and calculations in relation to the breadth of the umbra, and the manner of their appearance and disappearance, the doctor was led to the conclusion that the *depth* of the nucleus or dark part of the spots was, in several instances, from 2000 to nearly 4000 miles. In order to confirm his theory, he constructed a globe representing the sun, with certain hollows cut out to represent the spots or excavations, which were painted black with Indian ink, and the slope or shelving sides of the excavations were distinguished from the brightness of the external surface by a shade of the pencil, which increased toward the external border. When this artificial sun was fixed in a proper frame, and examined at a great distance with a telescope, the umbra and the nucleus exhibited the same phenomena which are observed on the real sun.*

Sir William Herschel, with his powerful telescopes, made numerous observations on the solar spots, and arrived at the same conclusion as Dr. Wilson had done, that the dark nucleus of the spots is the opaque body of the sun appearing through the openings in its atmosphere, and that the luminous surface of the sun is neither a liquid substance nor an elastic fluid, but luminous or phosphoric clouds floating in the solar atmosphere. He conceives, from the uniformity of color in the penumbra or *shallows*, that below these self-luminous clouds there is another stratum of clouds of inferior brightness, which is intended as a curtain to protect the solid and opaque body of the sun from the intense brilliancy and heat of the luminous clouds; and that "the luminous strata are sustained far above the level of the solid body by a transparent elastic medium, carrying on its upper surface, or at some considerably lower level within its depth, a cloudy stratum, which, being strongly illuminated from above, reflects a considerable portion of the light to our eyes, and forms a penumbra, while the solid body, shaded by the clouds, reflects little or none."

What, then, are the conclusions which may be deduced in regard to the constitution of the sun? In the first place, we must admit that, at present, we know very little of the nature of this immense luminary, and of the processes that are going forward on its surface or in its atmosphere. For there is no similar body with which we are intimately acquainted with which we can compare it, and which might enable us to form some definite conceptions of the causes which produce the phenomena it presents. But, secondly, it appears highly probable, if not absolutely certain, that the great body of the sun consists of an opaque solid globe, most probably diversified with elevations and depressions, but of the nature or qualities of this interior globe, and the materials of which it is composed, we are altogether unacquainted. Thirdly, that this opaque globe is surrounded with a body of light, which it diffuses throughout the planetary system and far beyond it; but whether this light consists of phosphoric clouds in perpetual motion, or how it is produced and kept continually in action, is only matter of conjecture. But, in whatever it consists, it is pretty evident that it forms a shell or covering around the dark body of the sun of several thousand miles in thickness. Fourthly, there are stupendous motions and operations continually going forward in connection with the surface or the luminous atmosphere of this immense body.

That extensive and amazing operations and processes are going forward on the surface of the sun, or in its immediate vicinity, appears from the immense size of both the dark and luminous spots, and the sudden and extensive changes to which they are frequently subjected. Spots have been observed on the solar disc so large as the one twentieth of the sun's diameter, and, of course, 44,000 miles in lineal extent, comprising an area of one thousand five hundred and twenty millions of square miles. Now it is known from observation that such spots seldom or never last longer than forty-four days, and, consequently, their borders must approach at the rate of at least a thousand miles every day, but in most cases with a much more rapid motion. What, then, shall we think of the motions and operations by which a large spot has been made to disappear in the course of twenty-two hours, as I have sometimes observed, yea, which have disappeared in the course of a single hour? And what shall we think of the process by which a spot as large as the earth was broken into two during the moment of observation, and made to recede from each other, as was observed both by Dr. Long and Dr. Wollaston? (See page 79.) How powerful the forces, how rapid the motions, and how extensive the changes which must have been produced in such cases! Whether we consider such changes to be produced in the solid globe of the sun, or in the luminous atmosphere with which it is environed, the scale on which such movements and operations must be conducted is immense, and altogether overpowering to the imagination. What should we think were we to behold the whole of the clouds which float in the earth's atmosphere dissipated in a moment; the continent of America detached from its basis and transported across the Atlantic; or the vast Pacific ocean, in the course of a few days, overwhelming with its billows the whole of Asia, Africa, and Europe? Amazing as such changes and revolutions would appear, there are, in all probability, operations and changes, though of a very different description, taking place on the solar surface or atmosphere upon a scale of much larger extent. It is found by calculation that the smallest space containing a visible area which can be distinctly perceived on the sun with good telescopes is about 460 miles; and a circle of this diameter contains about 166,000 square miles.

---

* See an elaborate paper on this subject by Dr. Wilson, in vol. lxiv of the "Philosophical Transactions;" and another, in reply to some objections of La Lande, in the volume for 1783.

Now those ridges or corrugations, formerly termed *faculæ*, which are seen near the sun's margin, are more than twenty times larger than such a space; they evidently appear to be elevations and depressions on the solar surface, and are almost as distinctly perceptible as the wavings and inequalities on the surface of the moon. How immensely large and elevated, then, must such objects in reality be, when we perceive their inequalities so distinctly at the distance of ninety-five millions of miles! The elevated parts of such objects cannot be less than several hundreds of miles above the level of the valleys or depressions, and extending in length several thousands of miles. Yet, sometimes in a few days, or, at most, a few weeks, these extensive objects are either dissipated or dark spots appear in their room.

It is evident, then, that stupendous powers are in action, and vast operations are going on in connection with this august luminary, far surpassing everything within the range of our contemplation in this terrestrial sphere, and of which the human mind can form no distinct conception. These operations appear to be carried forward in a systematic order, and by the regular influence of certain physical agents. But what these agents are; how they produce their effects; wherein they differ in their nature and properties from the physical agents connected with our globe; whether they be employed in keeping up a constant efflux of light and heat to the worlds which roll around; or whether their activities have any relation to intelligent beings connected with the sun, are questions which, in our present state, it is impossible to resolve. But we can easily conceive that scenes of overpowering grandeur and sublimity would be presented to view could we suppose ourselves placed in the immediate vicinity of this luminary. Were we placed within a hundred miles of the solar luminous atmosphere, where the operations which we now behold at a remote distance would be distinctly perceived, we should doubtless behold a scene of overpowering magnificence and splendor, and a series of sublime phenomena far surpassing what "eye hath yet seen," or the mind of man can yet conceive. Were we placed within this luminous atmosphere, on the solid surface of the sun, we should doubtless contemplate a scene altogether novel, and still more brilliant and astonishing. To a spectator in this position an opening in the luminous atmosphere several thousands of miles in circumference, where none appeared before, would be presented to his view, through which the stars of heaven might possibly be perceived; and in a short time this opening would gradually close, and he would find himself again surrounded with ineffable splendor; while, at the same time, he might have a view of the physical agents by which these astonishing effects are produced. In a short time another opening of a different kind would be perceived, and other scenes and transformations would be exhibited to the view in regular succession. That such scenes would actually be exhibited is a natural deduction from the theory (which may be considered as established) that the sun consists of a solid globe, surrounded with a luminous atmosphere, and that the dark spots are the openings in that luminous fluid

It appears, then, that the sun which we daily behold is a body of ineffable magnitude and splendor, and that the most magnificent operations are incessantly going forward on its surface or in its immediate vicinity. It is, indeed, a kind of *universe* in itself, the magnitude, and extent, and grandeur of which, and the vast and sublime operations connected with its physical constitution, surpass the powers of the human mind to form any adequate conception. We are destitute of a *substratum* of thought for enabling us to form a comprehensive conception on this subject. When we ascend to the top of Mount Etna or Mount Blanc, and survey the vast group of surrounding objects which appear around and beneath us when the morning sun illuminates the landscape, we behold one of the largest and most expansive objects that can meet our eye in this sublunary scene; and we can compare it with objects that are smaller and with those that are somewhat larger. But the amplitude of such a scene extends only to a hundred or a hundred and fifty miles in every direction, which is less than the least visible point or spot which we can perceive on the sun with the most powerful telescopes. Were we transported to a point five or six thousand miles above the surface of the earth, so as to take in nearly at one view the whole hemisphere of our globe; and were our eyes to be strengthened so as to be able to perceive every part of its surface distinctly, our ideas of *magnitude* would be vastly enlarged, and we should be enabled to form more correct and comprehensive conceptions than we can now do of the still greater magnitudes of many of the celestial bodies. But even such an object as the whole of the earth's hemisphere, seen at one comprehensive view, would afford us comparatively little assistance in forming an adequate conception of such a stupendous globe as the sun; it would not equal the idea of magnitude which we ought to attach to one of the smaller spots on its surface. For the area of the solar surface is twenty-four thousand seven hundred times greater; so that 24,700 scenes equal in magnitude to the hemisphere of our globe must pass between us in review before we could acquire a comprehensive and adequate idea of the expansive surface of the sun. And were a scene of this description to pass before our eyes every two hours, until an extent equal to the area of the sun passed under our view, and were twelve hours every day allotted for the observation, it would require more than eleven years before such a rapid survey of this vast luminary could be completed. But, as we can have no adequate idea of a scene comprehending a whole hemisphere of our globe, let us compare the view from Mount Etna with the amplitude of the sun. "There is no point on the surface of the globe," says Mr. Brydone, "that unites so many awful and sublime objects as the top of Etna, and no imagination has dared to form an idea of so glorious and magnificent a scene. The body of the sun is seen rising from the ocean, immense tracts both of sea and land intervening; the islands of Pinari, Alicudi, Lipari, Stromboli, and Volcano, with their smoking summits, appear under your feet, and you look down on the whole of Sicily as on a map, and can trace every river through all its windings from its source to its mouth. The view is absolutely boundless on every side, so that the sight is everywhere lost in the immensity." Yet this glorious and expansive prospect is comprised within a circle about 240 miles in diameter and 754 in circumference, containing 45,240 square miles, which is only 1-53,776,608th part of the surface of the sun; so that fifty-three millions, seven hundred and seventy-six thousand landscapes, such as beheld from Mount Etna, behooved to pass before us before we could contemplate a surface as expansive as that of the sun; and if every such landscape were to occupy two hours in the contemplation, as supposed above, it would require *twenty-four thousand five hundred and fifty-four years* before the whole surface of this immense globe could be in this manner surveyed; and, after all, we should have but a very imperfect conception of the *solid contents* of the sun, which contains 356,818,739,200,000,000 of cubical miles, which number is 146,670 times greater than the number of square miles upon its surface.

What a glorious idea, then, does such an object as the sun present to us of the GRANDEUR of the Deity and the ENERGIES of OMNIPOTENCE! There is no single object within the range of our knowledge that affords a more striking and august emblem of its Great Creator. In its luster, in its magnitude, in its energy, in its boundless influence, and its beneficial effects on this earth and on surrounding worlds, there is a more bright display of Divine perfection than in any other material being with which we are acquainted:

> "Great source of day! best image here below
> Of thy Creator! ever pouring wide
> From world to world, the vital ocean round,
> On Nature write, with every beam, his praise"

Could such a magnificent orb have been produced by a fortuitous concourse of atoms, and placed in its proper position to distribute light and attractive influence to the worlds which roll around it? Could chance have directed the distance at which it should be placed from the respective planets, or the size to which it should be expanded, in order to diffuse its energies to the remotest part of the system? Could chance have impressed upon it the laws requisite for sustaining in their courses all the bodies dependent upon it, or have endowed it with a source of illumination which has been preserved in action from age to age? To affirm such positions would be to undermine and annihilate the principles of all our reasonings. The existence of the sun proves the existence of an Eternal and Supreme Divinity, and at the same time demonstrates his omnipotent power, his uncontrollable agency, the depths of his wisdom, and the riches of his beneficence. If such a luminary be so glorious and incomprehensible, what must its Great Creator be? If its splendor be so dazzling to our eyes, and its magnitude so overpowering to our imagination, what must He be who lighted up that magnificent orb, and bade a retinue of worlds revolve around it; who "dwells in light inaccessible, to which no mortal eye can approach?" If the sun is only one out of many myriads of similar globes dispersed throughout the illimitable tracts of creation, how great, how glorious, how far surpassing human comprehension must be the plans and the attributes of the infinite and eternal Creator! "His greatness is unsearchable, and his ways past finding out." Could we thoroughly comprehend the depths of his perfections or the grandeur of his empire, he would cease to be God, or we should cease to be limited and dependent beings. But, in presenting to our view such magnificent objects, it is evidently his intention that we should rise in our contemplations from the effect to the cause, from the creature to the Creator, from the visible splendors and magnificence of creation to the invisible glories of Him who sits on the throne of the universe, "whose kingdom ruleth over all, and before whom all nations are counted as less than nothing and vanity."

It might here form a subject of inquiry, *whether there be any reason to believe that the sun is inhabited?* Most astronomers have been disposed to answer this question in the negative. Sir W. Herschel, however, and several others, consider it as not altogether improbable that the sun is peopled with rational beings. Viewing this luminary as consisting of a dark solid nucleus, surrounded by two strata of clouds, the outermost the region of that light and heat which is diffused to the remotest parts of the system, they conceived that the interior stratum was intended to protect the inhabitants of the sun from the fiery blaze of the sphere of light and heat with which they are surrounded. On either side of this question it becomes us to speak with diffidence and modesty. We ought not to set limits to the wisdom and arrangements of the Creator by affirming that rational beings could not exist and find enjoyment on such a globe as the sun, on account of the intensity of light and heat which forever prevails in that region. For it is probable that the luminous matter that encompasses the solid globe of the sun does not derive its splendor from any intensity of heat. If this were the case, the parts underneath, which are perpetually in contact with that glowing matter, would be heated to such a degree as to become luminous and bright, whereas we find that they have uniformly a *dark* appearance: so that it is possible the interior region of the sun may be in a state of comparatively low temperature. For anything we know to the contrary or can demonstrate, the sun may be one of the most splendid and delightful regions of the universe, and scenes of magnificence and grandeur may be there displayed far surpassing anything that is to be found in the planets which revolve around it, and its population may as far exceed in number that of other worlds as the immense size of this globe exceeds that of all the other bodies in the system. But, on the other hand, we know too little of the nature and constitution of the sun, and the plans of Divine Wisdom, to warrant us to make any positive assertions on this point. Although no intelligent beings were connected with this great luminary, its boundless influence in the planetary system; its being the soul and center of surrounding worlds; its diffusing light, and heat, and genial influences of various kinds, to all the tribes of their inhabitants; and its cementing them all by its attractive energy in one harmonious system, are reasons sufficient for the creation of this vast globe, without the influence of which perpetual darkness would ensue, the planets would start from their spheres, and the whole system soon become one universal wreck.

It is owing to the existence of the sun that our globe is a habitable world and productive of enjoyment. Almost all the benign agencies which are going forward in the atmosphere, the waters, and the earth, derive their origin from its powerful and perpetual influence. Its light diffuses itself over every region, and produces all that diversity of coloring which enlivens and adorns the landscape of the world, without which we should be unable to distinguish one object from another. By its vivifying action, vegetables are elaborated from inorganic matter, the sap ascends through their myriads of vessels, the flowers glow with the richest hues, the fruits of autumn are matured, and become, in their turn, the support of animals and of man. By its heat the waters of the rivers and the ocean are attenuated and carried to the higher regions of the atmosphere, where they circulate in the form of vapor until they again descend in showers, to supply the sources of the rivers and to fertilize the soil By the same agency all winds are produced, which purify the atmosphere by keeping it in perpetual motion, which propel our ships across the ocean, dispel noxious vapors, prevent pestilential effluvia, and rid our habitations of a thousand nuisances. By its attractive energy the tides of the ocean are modified and regulated, the earth conducted in its annual course, and the moon sustained and directed in her motions. Its influence descends even to the mineral kingdom, and is felt in the chemical compositions and decompositions of the elements of nature. The disturbances in the electric equilibrium of the atmosphere, which produce the phenomena of thunder, lightning, and rain, and the varieties of terrestrial magnetism; the slow degradation of the solid constituents of the globe and their diffusion among the waters of the ocean, may all be traced, either directly or indirectly, to the agency of the sun. It illuminates and cheers all the inhabitants of the earth from the polar regions to the torrid zone. When its rays gild the eastern horizon after the darkness of the night, something like a new creation appears. The landscape is adorned with a thousand shades and colors; millions of insects awake and bask in its rays; the birds start from their slumbers, and fill the groves with their melody; the flocks and herds express their joy in hoarser acclamations; "man goeth forth to his work and to his labor;" all nature smiles, and "the hills rejoice on every side." Without the influence of this august luminary, a universal gloom would ensue, and surrounding worlds, with all their trains of satellites, would be shrouded in perpetual darkness. This earth would become a lifeless mass, a dreary waste, a rude lump of inactive matter, without beauty or order. No longer should we behold the meadows clothed with verdure, the flowers shedding their perfumes, or "the valleys covered with corn." The feathered songsters would no longer chant their melodious notes; all human activity would cease; universal silence would reign undisturbed, and this huge globe of land and water would return to its original chaos.

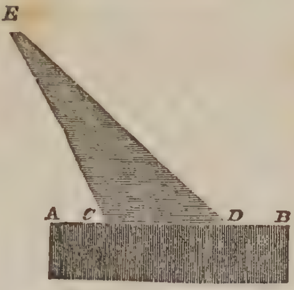
Hence it appears that there is a sufficient reason for the creation of this powerful luminary, although no sensitive or intelligent beings of any description were placed on its surface. But, at the same time, when we consider the infinite wisdom and intelligence of the Divine mind, and that the thoughts and the ways of God as far surpass the thoughts of man as the heavens in hight surpass the earth; when we consider that animated beings on our own globe are found in situations where we should never have expected them; that every puddle and marsh, and almost every drop of water, is crowded with living beings; and that even the very viscera in the larger animals can afford accommodation for sentient existence, it would be presumptuous in man to affirm that the Creator *has not placed* innumerable orders of sentient and intelligent beings, with senses and constitutions accommodated to their situations, throughout the expansive regions of the sun.

It has been a question which has exercised the attention of some astronomers, *whether the solar phenomena have any effect upon the weather*, or the productiveness of our seasons. Sir W. Herschel was of opinion, that when the corrugations and openings of the solar atmosphere are numerous, the heat emitted by the sun must be proportionably increased, and that this augmentation must be perceptible by its effects on vegetation; and, by comparing the solar appearances as given by La Lande with the table of the price of wheat in Smith's "Wealth of Nations," he obtained results which he considered as favorable to his hypothesis. But it is evident that we are not yet in possession of such a series of facts in relation to this subject as will warrant us to draw any general conclusions. Beside, we know too little of the construction of the sun, and the nature of those processes which are going on in its atmosphere, to be able to determine the proportion of light and heat which particular phenomena indicate. So far as my own observation goes, I should be disposed to adopt an opposite conclusion, namely, that in those years when the spots of the sun are numerous, the seasons are colder and more unproductive of vegetation. This was remarkably the case in the year 1816, when the solar spots were extremely numerous, and when the harvest was so late and scanty, that the price of all kinds of grain was more than double what it had been before or what it has been since. The year 1836, and the present year, 1837, afford similar examples; for, during eighteen months past, the solar spots have been more numerous than in any other period in my recollection; and the cold of the summer and harvest of 1836, and of the winter and spring of 1837, and its unfavorable effects on vegetation, were greater than what had been experienced for more than twenty years before. But on this point we are not yet warranted to draw any positive conclusions. Before we can trace any general connection between the solar spots and the temperature and vegetation of our globe in any particular season, we must endeavor to ascertain the effects produced on vegetation not only in two or three particular countries which lie adjacent to each other, but over all the regions of the earth. It may be proper to direct our future observations to this point, as they might probably lead to some important results; but a considerable period behooved to elapse before we could be warranted to deduce any definite conclusions.

Whether the sun has a progressive motion in absolute space is another question which has engaged the attention of astronomers. If the sun have such a motion directed to any quarter of the heavens, the stars in that quarter must apparently recede from each other, while those in the opposite region will seem gradually to approach. Sir W. Herschel found that the apparent proper motion of forty-four stars out of fifty-six are very nearly in the direction which should result from a motion of the sun toward the constellation *Hercules*, or to a point of the heavens whose right ascension is 250° 52½′, and north declination 49° 38′. "No one," says Sir John Herschel, "who reflects with due attention on the subject, will be inclined to deny the high probability, nay, *certainty*, that the sun *has* a proper motion in *some* direction." But it appears to be yet undetermined by modern astronomers to what point in the heavens this motion is directed, and whether it be in a straight line or in a portion of the circumference of an immense circle If the sun, then, has a proper motion in space, all the planetary bodies and their satellites, along with the comets, must partake of it; so that, beside their own proper motions around this luminary, they are likewise carried along with the sun through the depths of infinite space with a velocity perhaps as great as that with which they are carried round in their orbits. Our earth will therefore partake of three motions: one round its axis, another round the sun, and a third in the direction in which the sun is moving, and, consequently, it is probable that we shall never again occupy that portion of absolute space through which we are now passing throughout all the succeeding periods of eternity

The Zodiacal Light.—The zodiacal light is a phenomenon which has been generally considered as connected with the sun. The light appears to have been noticed by Mr. Childrey about the year 1660; but it was afterward more particularly noticed and described by Cassini in the spring of 1683, which was the first time he had seen it, and he observed it for about eight days. It appears generally in a conical form, having its base directed toward the body of the sun and its point toward some star in the zodiac. Its light is like the milky way, or that of the faint twilight, or the tail of a comet, thin enough to let the stars be seen through it, and seems to surround the sun in the form of a lens, the plane of which is nearly coincident with the plane of the sun's equator.—The apparent angular distance of its vertex from the sun varies from 40 to 90 degrees, and the breadth of its base, perpendicular to its axis, from 8 to 30 degrees. It is supposed to extend beyond the orbit of Mercury, and even as far as that of Venus, but never so far as the orbit of the earth. This light is weaker in the morning when day is coming on than at night when darkness is increasing, and it disappears in full moonlight or in strong twilight. In north latitudes it is most conspicuous after the evening twilight about the end of February and the beginning of March; and before the appearing of the morning twilight, about the beginning of October; for at those times it stands most erect above the horizon, and is therefore farthest removed from the thick vapors and the twilight. About the time of the winter solstice it may likewise be seen in the mornings; but it is seldom perceptible in summer on account of the long twilights. It is more easily and more frequently perceived in tropical climates, and particularly near the equator, than in our country, because in those parts the obliquity of the equator and zodiac to the horizon is less, and because the duration of twilight is much shorter. Humboldt observed this light at Caraccas, on the 18th of January, after seven o'clock in the evening. The point of the pyramid was at the hight of 53 degrees; and the light totally disappeared about half past nine, about 3¾ hours after sunset, without any diminution in the serenity of the sky. On the 15th of February it disappeared 2 hours and 50 minutes after sunset, and the altitude of the pyramid on both these occasions was 50 degrees. The following figure exhibits a view of this phenomenon as it is seen about the beginning of March, at seven o'clock in the evening, when the twilight is ending, and the equinoctial point in the horizon. *A B* represents the horizon; *C D* the base of the luminous triangle; and *E* its apex, pointing toward the Pleiades or the star Aldebaran, its axis forming an angle of between 60 and 70 degrees with the horizon.

Fig. 77.



Various opinions have been entertained as to the cause of this phenomenon; but as it uniformly accompanies the sun, it has been generally ascribed to an atmosphere of immense extent surrounding that luminary, and extending beyond the orbit of Mercury. According to this opinion, the zodiacal light is considered as a section of this atmosphere; but this opinion now appears extremely dubious. Professor Olmsted, of Yale College, the celebrated Arago, Biot, and others, are now disposed to identify this phenomenon with the cause that produces the "November Meteors," or shooting stars, which have, of late, excited so great a degree of public attention. It appears highly probable that these meteors derive their origin from a nebulous body which revolves round the sun, and which, in certain parts of its course, comes very near the orbit of the earth, so as to be within its attractive power; and if such a body be the source whence these meteors proceed, it may also account for the phenomena of the zodiacal light. The subject is worthy of particular attention, and future observations may not only throw light on this particular phenomenon, but open to our view a species of celestial bodies with which we were formerly unacquainted.

CHAPTER IV.

ON THE SECONDARY PLANETS OR MOONS.

Having, in the preceding chapter, given a detailed account of the phenomena connected with the sun and the primary planets of our system, I shall now proceed to a brief description of what is known in reference to the satellites or moons which accompany several of the primary planets.

A secondary planet or satellite is a body which revolves around a primary planet as the center of its motion, and which is at the same time carried along with its primary round the sun. The satellites form a system, in connection with their primaries, similar to that which the planets form in connection with the sun. They revolve at different distances from their primaries; they are regulated according to the laws of Kepler formerly alluded to; their orbits are circles or ellipses of very moderate eccentricity; in their motions around their primaries they describe areas very nearly proportional to the times; and the squares of the periodical times of all the satellites belonging to each planet are in proportion to each other as the cubes of their distances (see page 23) The planets around which satellites have been discovered, are, the earth, Jupiter, Saturn, and

Uranus. Of the satellites belonging to these bodies I shall present a brief sketch in the order in which they are here mentioned.

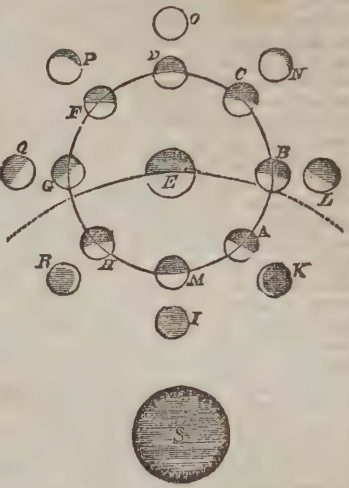
I. OF THE EARTH'S SATELLITE, OR THE MOON.

Before proceeding to a particular description of this nocturnal luminary, I shall present a brief sketch of its *apparent motions*.

The moon, like all the other celestial bodies, appears daily to rise in an easterly direction, and to set in the western parts of the horizon. Its apparent motion in this respect is similar to that of the sun, formerly described, and is owing to the diurnal motion of the earth. Its *real motion* round the earth is in a contrary direction, namely, from west to east, or in the same direction in which all the planets move round the sun. This motion may be traced every lunation, but more distinctly during the spring months, when the moon, in the first quarter, appears in a high degree of north declination, and when its crescent is sometimes visible within thirty-six hours of the change. About this period, on the second or third day of the moon's age, it will be seen in the west after sunset at a small elevation above the horizon, and exhibiting the form of a slender crescent. On the next evening it will appear at a still higher elevation at the same hour, having moved about thirty degrees farther to the east, and its crescent will appear somewhat larger. Every succeeding day it will appear at a greater elevation, and farther to the east than before, and its crescent will appear larger, until about the seventh or eighth day, when it will be seen in the south when the sun is setting in the west, at which time it assumes the appearance of a semicircle, or half moon. During this period the horns of the crescent point toward the east, the enlightened part of the lunar disc being turned toward the sun. After the first quarter, or the period of half moon, the lunar orb still keeps on its course to the eastward, and the portion of its enlightened disc is gradually enlarged, until about the fifteenth day of the moon's age, when it appears as a full enlightened hemisphere, and rises in the east about the time when the sun is setting in the west. In this position it is said to be in *opposition* to the sun, and passes the meridian about midnight. After this period the enlightened part of its disc gradually diminishes, and it rises at a late hour, until, in the course of seven days, it is again reduced to a semicircle, and is seen only during one half of the night. Some nights after it appears reduced to a crescent, having its points or horns turned toward the *west*, the sun being then to the east of it. After this it rises but a little time before the sun, and is seen only early in the morning; and its crescent daily diminishes until it at length disappears, when it rises at the same time with the sun; and after having been invisible for two or three days, it reappears in the evening in the west a little after sunset. During this period the moon has made a complete circuit round the heavens from west to east, which is accomplished in twenty-nine days and a half, in which period it passes through all the phases now described. The progressive motion from west to east, every day, may be traced by observing the stars which lie nearly in the line of the moon's course. If a star be observed considerably to the eastward of the moon on any particular evening, on the following evening it will appear about thirteen degrees nearer the star, and will afterward pass to the eastward of it, and every succeeding day will approach nearer to all the other stars which lie near the line of its course to the eastward The reason why the moon appears under the different phases now described will appear from the following figure.

In this diagram *S* represents the sun; *E* the earth; and *M*, *A*, *B*, *C*, *D*, *F*, *G*, *H*, the moon in different positions in its orbit round the earth. When the moon is at *M*, as seen from the earth, her dark side is completely turned to the earth; and she is consequently invisible, as at *I*, being nearly in the same part of the heavens with the sun. She is in this position at the period termed *new moon*, when she is also said to be *in conjunction* with the sun. When she has moved from *M* to *A* a small part of her enlightened hemisphere is turned toward the earth, when she appears in the form of a *crescent*, as at *K*. In moving from *A* to *B* a larger portion of her enlightened hemisphere is gradually turned toward the earth; and when she arrives at *B* the one-half of her enlightened hemisphere is turned to the earth, and she assumes the figure of a *half moon*, as at *L*. When arrived at *C* she appears under what is called a *gibbous* phase, as at *N*, more than one-half of her enlightened disc being turned to the earth. At *D* her whole enlightened hemisphere is turned to our view, and she appears a *full moon*, as at *O*. After this period she again decreases, turning every day less and less of her enlightened hemisphere to the earth, so that at *F* she appears as at *P*; at *G* a half-moon on the decline, as at *Q*; at *H* a crescent, as at *R*; and at *M* she is again in conjunction with the sun, when her dark side is turned to the earth as before. The moon passes through all these changes in twenty-nine days, twelve hours, and forty-four minutes, at an average, which is termed her *synodical revolution*. But the time which she takes in making one revolution round the earth, from a fixed star to the same again, is only twenty-seven days, seven hours, and forty-three minutes, which is called her *periodical revolution*. For, after one revolution is finished, she has a small arc to describe in order to get between the sun and the earth; because, in consequence of the earth's motion in the same direction, the sun appears to be advancing forward in the ecliptic, and, of course, the moon requires some time to overtake him, after having finished a revolution. This surplus of motion occupies

Fig. 78.



two days, five hours, and one minute, which, added to the periodical, make the synodical revolution, or the period between one new or full moon and another. This might be illustrated by the revolution of the hour and minute-hands of a watch or clock. Suppose the hour-hand to represent the sun, and a complete revolution of it to represent a year; suppose the minute-hand to represent the moon, and its circuit round the dial-plate a month, it is evident that the moon or minute-hand must go more than round the circle where it was last conjoined with the sun or hour-hand before it can again overtake it. If, for example, they were in conjunction at 12, the minute-hand or moon must make a complete revolution and above one-twelfth before they can meet, a little past I; for the hour-hand, being in motion, can never be overtaken by the minute-hand at that point from which they started at their last conjunction.

To a spectator placed on the lunar surface, the earth would every month exhibit all the phases of the moon, but in a reverse order from what the moon exhibits to the earth at the same time. Thus (Fig. 78), when the moon is at *D* only the dark hemisphere of the earth is turned toward the moon, and, consequently, the earth would be then invisible; so that when it is full moon to us, it is new moon to a lunar inhabitant; as the earth will then be in conjunction with the sun, and nothing but its dark hemisphere presented to view. When the moon is at *P* a small portion of the enlightened half of the earth is turned toward the moon, and it appears as a crescent. When she is at *Q* the earth appears as a half-moon; when at *R*, a gibbous phase; and when she is at I, the time of new moon to us, the earth then shines on the dark side of the moon with a full enlightened hemisphere. It is owing to this circumstance, that when the new moon first appears like a slender crescent, her dark hemisphere is seen illuminated with a faint light, perceptible even to the naked eye; and with the help of a telescope we are enabled, by this faint illumination, to distinguish the prominent spots on this portion of the lunar disc. This faint light, therefore, is nothing else than *the moonlight of the moon*, produced by the earth shining with nearly a full face upon the dark surface of the moon. And as the surface of the earth is thirteen times larger than the surface of the moon, the light reflected from the earth will be nearly equal to that of thirteen full moons. As the age of the moon increases, this secondary light is gradually enfeebled, and after the seventh or eighth day from the change it is seldom visible. This arises from the diminution of the enlightened part of the earth, which then appears only like a half-moon, approaching to a crescent, and consequently, throws a more feeble light upon the moon, which is the more difficult to be perceived as the enlightened part of the moon increases.

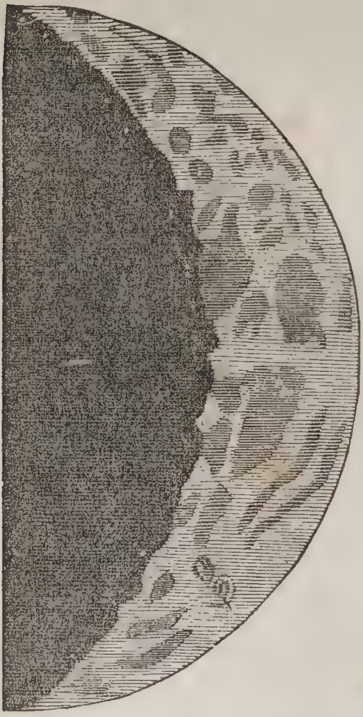
Rotation of the Moon.—While the moon is performing her revolution round the earth every month, she is also gradually revolving round her axis; and it is somewhat remarkable that her revolution round her own axis is performed in *the same time* as her revolution round the earth. This is inferred from the circumstance that *the moon always turns the same face to the earth*, so that we never see the other hemisphere of this globe. For if the moon *had no rotation upon an axis*, she would present every part of her surface to the earth. This does not, at first sight, appear obvious to those who have never directed their attention to the subject. Any one, however, may convince himself of the fact by standing in the center of a circle, and causing another person to carry round a terrestrial globe, without turning it on its axis, when he will see every part of the surface of the globe in succession; and in order that one hemisphere only should be presented to his view, he will find that the globe will require to be gradually turned round its axis, so as to make a complete rotation during the time it is carried round the circle. The axis of the moon is inclined 88° 29′ to the ecliptic, so that it is nearly perpendicular to it. Although the moon presents nearly the same side to the earth in all its revolutions around it, yet there is perceived a certain slight variation in this respect. When we look attentively at the disc of the moon with a telescope, we sometimes observe the spots on her eastern limb, which were formerly visible concealed behind her disc, while others appear on her western limb which were not seen before. The spots which appear on the western limb withdraw themselves behind the limb, while the spots which were concealed behind the eastern limb again appear. The same phenomena are observed in the north and south limb of the moon, so that the spots sometimes change their positions about three minutes on the moon's disc, or about the eleventh part of her diameter. This is termed *the libration of the moon;* the one her libration in *longitude*, and the other her libration in *latitude.*

From what we have stated above in relation to the phases and motions of the moon, it is evident that the moon is a dark body, like the earth, and derives all its light from the sun, for its enlightened side is always turned toward that luminary. It likewise derives a faint light by the reflection of the sun's rays from the earth, in the same way as we derive a mild light from the moon. And as the earth has an uneven surface, composed of mountains and vales, so the moon is found to be diversified with similar inequalities. It is owing to these inequalities, or the *roughness* of the moon's surface, that the light of the sun is reflected from it *in every direction;* for, if the surface of the moon were perfectly smooth, like a polished globe or speculum, her orb would be invisible to us; except, perhaps, at certain times, when the image of the sun, reflected from it, would appear like a bright lucid point. This may be illustrated by the following experiment. Place a silver globe, perfectly polished, about two inches diameter, in the sun; the rays which fall upon it being reflected variously, according to their several incidences, upon the convex surface, will come to our eye only from one point of the globe, which will therefore appear a small bright spot, but the rest of the surface will appear dark. Let this globe then be boiled in the liquor used for whitening silver, and placed in the sun; it will appear in its full dimensions all over luminous; for the effect of that liquor is to take off the smoothness of the polish, and make the surface rough, and then every point of it will reflect the rays of light in every direction.

The moon is nearest to the earth of all the celestial bodies, and is a constant attendant upon it at all seasons. Her distance from the center of the earth is, in round numbers, 240,000 miles, or somewhat less than a quarter of a million; which is little more than the fourth part of the diameter of the sun. Small as this distance is compared with that of the other planets, it would require five hundred days, or sixteen months and a half, for a steam-carriage to move over the interval which separates us from the lunar orb, although it were moving day and night at the rate of twenty miles every hour. In her motion round the earth every month, she pursues her course at the rate of 2300 miles an hour. But she is carried at the same time, along with the earth, round the sun every year, so that her real motion in space is much more rapid than what has now been stated; or while she accompanies the earth in its motion round the sun, which is at the rate of 68,000 miles an hour, she also moves thirteen times round the earth during the same period, which is equal to a course of nearly twenty millions of miles.

The moon's orbit is inclined to the ecliptic in an angle of 5° 9′; so that, in one part of her course, she is above, and in another below the level of the earth's orbit. It is owing to this circumstance that this orb is not eclipsed at every full moon and the sun at every new moon, which would regularly happen did the moon move in an orbit exactly coincident with the plane of the ecliptic. The moon's orbit, of course, crosses the orbit of the earth in two opposite points, called her *nodes;* and it is only when the new or full moon happens at or near these nodes that an eclipse of the sun or moon can take place; for it is only when she is in such a position that the sun, the moon, and the earth are nearly in a straight line, and that the shadow of the one can fall upon the other. The shadow of the moon falling upon any part of the earth produces an eclipse of the sun, and the shadow of the earth falling upon the moon causes an eclipse of the moon. An eclipse of the moon can only take place at *full moon*, when the earth is between the sun and the moon; and an eclipse of the sun can only happen at *new moon*, when the moon comes between the sun and the earth. Lunar eclipses are visible in all parts of the earth which have the moon above their horizon, and are everywhere of the same magnitude and duration; but a solar eclipse is never seen throughout the whole hemisphere of the earth where the sun is visible; as the moon's disc is too small to hide the whole, or any part of the sun from the whole disc or hemisphere of the earth. Nor does an eclipse of the sun appear the same in all parts of the earth where it is visible, but when in one place it is total, in another it is only partial.

Fig. 79.



The moon's orbit, like those of the other planets, is in the form of an *ellipse*, the *eccentricity* of which is 12,960 miles, or about 1-37th part of its longest diameter. The moon is, therefore, at different distances from the earth in different parts of her orbit. When at the greatest distance from the earth, she is said to be in her *apogee;* when at the least distance, in her *perigee.* The nearer the moon is to the periods of *full* or *change*, the greater is her velocity; and the nearer to the quadratures, or the periods of half-moon, the slower she moves When the earth is in its *perihelion*, or nearest the sun, the periodical time of the moon is the greatest. The earth is at its perihelion in winter, and, consequently, at that time the moon will describe the largest circle about the earth, and her periodical time will be the longest; but when the earth is in its *aphelion*, or farthest from the sun, which happens in summer, she will describe a smaller circle, and her periodical time will be the least; all which circumstances are found to agree with observation. These and many other irregularities in the motion of this orb, which it would be too tedious to particularize, arise from the attractive influence of the sun upon the lunar orb in different circumstances and in different parts of its course, so as to produce different degrees of accelerated and retarded motion. The irregularities of the moon's motion have frequently puzzled astronomers and mathematicians, and they render the calculations of her true place in the heavens a work of considerable labor. No less than thirty equations require to be applied to the *mean* longitude in order to obtain the *true*, and about twenty-four equations for her latitude and parallax; but to enter minutely into such particulars would afford little satisfaction to general readers.

Description of the surface of the Moon, as seen through telescopes.—Of all the celestial bodies, the telescopic view of the moon presents the most interesting and variegated appearance. We perceive, as it were, a map or model of another world, resembling in some of its prominent features the world in which we dwell, but differing from it in many of its minute arrangements. It bears a certain analogy to the earth in some of the mountains and vales which diversify its surface; but the general form and arrangement of these elevations and depressions, and the scenery they present to the spectator on the lunar surface, are very different from what we behold in our terrestrial landscapes. When we view the moon with a good telescope when about three days old, we perceive a number of elliptical spots with slight shadows, evidently indicating elevations and depressions; we also perceive a number of bright specks or studs in the dark hemisphere, immediately adjacent to the enlightened crescent, and the boundary between the dark and the enlightened portion of the disc appears jagged and uneven. At this time, too, we perceive the dark part of the moon covered with a faint light; so that the whole circular outline of the lunar hemisphere may be plainly discerned. When we take a view of the lunar surface, at the period of half moon, we behold a greater variety of objects, and the shadows of the mountains and caverns appear larger and more prominent. This is, on the whole, the best time for taking a telescopic view of the surface of the moon. When we view her when advanced to a gibbous phase we see a still greater extent of the surface, but the shadows of the different objects are shorter and less distinct. At the time of full moon, no shadows either of the mountains or caverns are perceptible, but a variety of dark and bright streaks and patches appear distributed in different shapes over all its surface. If we had no other view of the moon but at this period, we should scarcely be able to determine whether mountains and vales existed on this orb. The view of the *full* moon, therefore, however beautiful and variegated, can give us no accurate idea of the mountains, vales, caverns, and other geographical arrangements which diversify its surface.

Lunar Mountains.—That the surface of the moon is diversified with mountains or high elevations, is evident from an inspection of its disc, even with a common telescope. They are recognized from various circumstances. 1. From the appearance of the boundary which separates the dark from the enlightened hemisphere of the moon. This boundary is not a straight line or a regular curve, as it would be if the moon were a perfectly smooth globe, but uniformly presents an uneven or jagged appearance, cut, as it were, into numerous notches and breaks somewhat resembling the teeth of a saw, which appearance can only be produced by elevations and depressions on the lunar surface (Fig. 79). 2. Adjacent to the boundary between light and darkness, and *within* the dark part of the moon, there are seen, in almost every stage of the moon's increase and decrease, a number of *shining points* like stars, completely separated from the enlightened parts, and sometimes other small spaces or streaks which join to the enlightened surface, but run out into the dark side, which gradually change their figure until at length they come wholly within the enlightened boundary. These shining points or streaks are ascertained to be the tops or highest ridges of mountains which the sun first enlightens before his rays can reach the valleys; just as the beams of the rising sun irradiate our mountain tops before the lower parts of the landscape are enlightened. 3. The *shadows* of the mountains, when they are fully enlightened, are distinctly seen near the border of the illuminated part of the moon, as the shadows of elevated objects are seen on the terrestrial landscape. These shadows are longest and most distinctly marked about the time of half-moon; and they grow shorter as the lunar orb advances to the period of full moon, in the same way as the shadows of terrestrial objects in summer gradually shorten as the sun approaches the meridian. These considerations demonstrate, beyond the possibility of doubt, that mountains of very considerable altitude and in vast variety of forms abound in almost every region of the moon.

The lunar mountains in general exhibit an arrangement and an aspect very different from the mountain scenery of our globe. They may be arranged into the four following varieties: 1. *Insulated mountains*, which rise from plains nearly level, like a sugar-loaf placed on a table, and which may be supposed to present an appearance somewhat similar to Mount Etna or the peak of Teneriffe. The shadows of these mountains, in certain phases of the moon, are as distinctly perceived as the shadow of an upright staff when placed opposite to the sun; and their hights can be calculated from the length of their shadows. The hights and the length of the base of more than seventy of these mountains have been calculated by M Schroeter, who had long surveyed the lunar face with powerful telescopes, and who some time ago published the result of his observations in a work entitled "Fragments of Selenography." Thirty of these insulated mountains are from 2 to 5 miles in perpendicular hight; thirteen are above 4 miles; and about forty are from a quarter of a mile to two miles in altitude. The length of their bases varies from 3½ to 96 miles in extent. Some of these mountains will present a very grand and picturesque prospect around the plains on which they stand. 2. *Ranges of mountains*, extending in length two or three hundred miles. These ranges bear a distant resemblance to our Alps, Apennines, and Andes, but they are much less in extent, and do not form a very prominent feature of the lunar surface. Some of them appear very rugged and precipitous, and the highest ranges are, in some places, above four miles in perpendicular altitude. In some instances they run nearly in a straight line from north-east to south-west, as in that range called the *Apennines;* in other cases they assume the form of a semicircle or a crescent. 3. Another class of the lunar mountains is the *circular ranges* which appear on almost every part of the moon's surface, particularly in its southern regions. This is one of the grand peculiarities of the lunar ranges, to which we have nothing similar in our terrestrial arrangements. A plain, and sometimes a large cavity, is surrounded with a circular ridge of mountains, which encompasses it like a mighty rampart. These annular ridges and plains are of all dimensions, from a mile to forty or fifty miles in diameter, and are to be seen in great numbers over every region of the moon's surface. The mountains which form these ridges are of different elevations, from one-fifth of a mile to 3½ miles in altitude, and their shadows sometimes cover the one-half of the plain. These plains are sometimes on a level with the general surface of the moon, and in other cases they are sunk a mile or more below the level of the

Fig. 80.

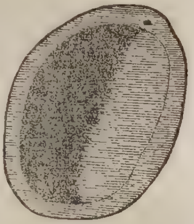


Fig. 81.

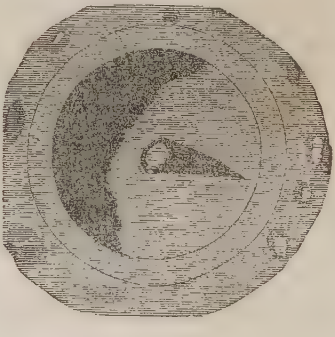

Fig. 82.

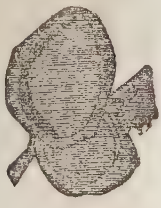

ground which surrounds the *exterior* circle of the mountains. In some of these circular ridges I have perceived a narrow *pass* or opening, as if intended to form an easy passage or communication between the interior plain and the regions beyond the exterior of the mountains. 4. The next variety is the *central mountains*, or those which are placed in the middle of circular plains. In many of the plains and cavities surrounded by annular mountains there is an insulated mountain, which rises from the center of the plain, and whose shadow sometimes extends, in a pyramidal form, across the semidiameter of the plain to the opposite ridges. These central mountains are generally from half a mile to a mile and a half in perpendicular altitude. In some instances they have two and sometimes three separate tops, whose distinct shadows can be easily distinguished. Sometimes they are situated toward one side of the plain or cavity, but, in the great majority of instances, their position is nearly or exactly central. The lengths of their bases vary from five to about fifteen or sixteen miles.

The preceding figures may perhaps convey a rude idea of some of the objects now described; but it is impossible, by any delineations, to convey an idea of the peculiarities and the vast variety of scenery which the lunar surface presents, such as is exhibited by a powerful telescope during the different stages of the increase and decrease of the moon.

Fig. 83.

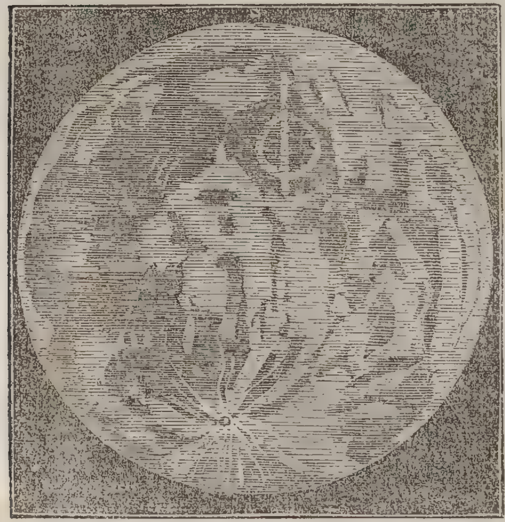

Fig. 79 represents the moon in a crescent phase, for the purpose of showing how the enlightened tops of the mountains appear on the dark part of the moon, detached as it were from the enlightened part, and likewise to show how the boundary between the light and darkness appears jagged and uneven, indicating the existence of elevations and depressions upon its surface. Fig. 80 represents a circular or elliptical range of mountains, surrounding a plain of the same shape, where the shadow of that side of the range which is opposite to the sun appears covering the half of the plain. Fig 81 represents a circular plain, with the shadow of one side of the mountains which encompass it, and a *central* mountain with its shadow in the same direction. Fig. 82 exhibits another of these circular ridges and plains. Several hundreds of these circular cavities and plains are distributed over the lunar surface, but they are most abundant in the southern regions.

Fig. 83 exhibits a pretty correct view of the full moon, as seen through a telescope magnifying above a hundred times, in which the darker shades represent, for the most part, the *level* portions of the moon's surface, and the lighter shades those which are more elevated or mountainous. The bright spot near the bottom, from which streaks or streams of light seem to proceed, is called *Tycho* by some, and *Mount Etna* by others. It consists of a large irregular cavity, surrounded by mountains; and the streaks of light are the elevated ridges of ranges of mountains, which seem to converge toward it as to a center. This is the most variegated and mountainous region of the lunar surface. Fig. 84 is a view of the moon, hastily taken, when in a gibbous phase. The shadows were then comparatively short, and it would require to be engraved on a much more extensive scale than our page admits to show distinctly the elevations and depressions at the boundary between light and darkness. Fig. 85 (Nos. 1 and 2) represent some detached spots near the line which separated the dark and enlightened parts of the moon.

From what has now been stated respecting the lunar mountains, it will evidently appear that there must be a great variety of sublime and picturesque scenery connected with the various landscapes of the moon. If the surface of that orb be adorned with a diversity of color and with something analogous to the vegetation of our globe, there must be presented to the view of a spectator in the moon a variety of scenes altogether dissimilar to those which we can contemplate on this earth. The circular plains and mountains will present three or four varieties of prospect, of which we have no examples on our globe. In the first place, a spectator near the middle of the plane will behold his view bounded on every hand by a chain of lofty mountains, at the distance of 5, 10, 15, or 20 miles, according to the diameter of the plain; and as the tops of these mountains are at different elevations, they will exhibit a *variety* of mountain-scenery. In the next place, when standing on the top of the central mountain, the whole plain, with its diversified objects, will be open to his view, which will likewise take in all the variety of objects connected with the circular mountain-range which bounds his prospect. A third variety of view will be presented in traveling round the plain, where the various aspects of the central mountain will present, at every stage, a new landscape and a diversity of prospect. Another view, still more extensive, will be obtained by ascending to the summit of the circular range, where the whole plain and its central mountain will be full in view, and a prospect will, at the same time, be opened of a portion of those regions which lie beyond the *exterior* boundary of the mountains (see Fig. 81). A diversity of scenery will likewise be presented by the *shadows* of the circular range and the central mountain. When the sun is in the horizon, the whole plain will be enveloped in the shadows of the mountains, even after daylight begins to appear. These shadows will grow shorter and shorter as the sun rises in the heavens; but a space of time equal to one or two of our days will intervene before the body of the sun is seen from the opposite side of the plain, rising above the mountain tops; and a still longer space of time before his direct rays are seen at the opposite extremity. These shadows are continually varying; during the increase of the moon they are thrown in one direction, and during the decrease in a direction exactly opposite; and it is only about the time of full moon that every part of the plain, and the mountains which surround it, are fully enlightened, and the shadows disappear. There must, therefore, be a far greater variety of sublime mountain-scenery, and of picturesque objects connected with it, on the lunar surface, than what is presented to our view in terrestrial landscapes.

The Lunar Caverns.—These form a very peculiar and prominent feature of the moon's surface, and are to be seen throughout almost every region; but are most numerous in the south-west part of the moon. Nearly a hundred of them, great and small, may be distinguished in that quarter. They are all nearly of a circular shape, and appear like a very shallow egg-cup. The smaller cavities appear within almost like a hollow cone, with the sides tapering toward the center; but the larger ones have, for the most part, flat bottoms, from the center of which there frequently rises a small steep conical hill, which gives them a resemblance to the annular ridges and central mountains above described. In some instances their margins are level with the general surface of the moon, but in most cases they are encircled with a high annular ridge of mountains marked by lofty peaks. Some of the larger of these cavities contain smaller cavities of the same kind and form, particularly in their sides. The mountainous ridges which surround these cavities reflect the greatest quantity of light; and hence that region of the moon in which they abound appears brighter than any other. From their lying in every possible direction, they appear, at and near the time of full moon, like a number of brilliant streaks or radiations. These radiations appear to converge toward a large brilliant spot surrounded by a faint shade, near the lower part of the moon, which is known by the name of *Tycho*, and which every one who views the full moon, even with a common telescope, may easily distinguish. In regard to their *dimensions*, they are of all sizes, from three miles to fifty miles *in diameter* at the top; and their depth below the general level of the lunar surface varies from one-third of a mile to three miles and a half. Twelve of these cavities, as measured by Schroeter, were found to be above two miles in perpendicular depth. These cavities constitute a *peculiar feature* in the scenery of the moon, and her physical constitution, which bears scarcely any analogy to what we observe in the physical arrangements of our globe. But, however different such arrangements may appear from what we see around us in the landscapes of the earth, and however unlikely it may at first sight appear that such places should be the abode of intelligent beings, I have no doubt that, in point of beauty variety, and sublimity, these spacious hollows, with all their assemblage of circular and central mountain-scenery, will exceed in interest and grandeur any individual scene we can contemplate on our globe. We have only to conceive that such places are diversified and adorned with all the vegetable scenery which we reckon beautiful and picturesque in a terrestrial landscape, and with objects which are calculated to reflect with brilliancy the solar rays, in order to give such an idea of the grandeur of the scene. And that the objects connected with these hollows are formed of substances fitted to reflect the rays of the sun with peculiar luster, appears from the brilliancy which most of them exhibit when either partially or wholly enlightened; presenting to view, especially at full moon, the most luminous portions of the lunar surface, so that former astronomers were led to compare them to rocks of diamond.

Fig. 84.

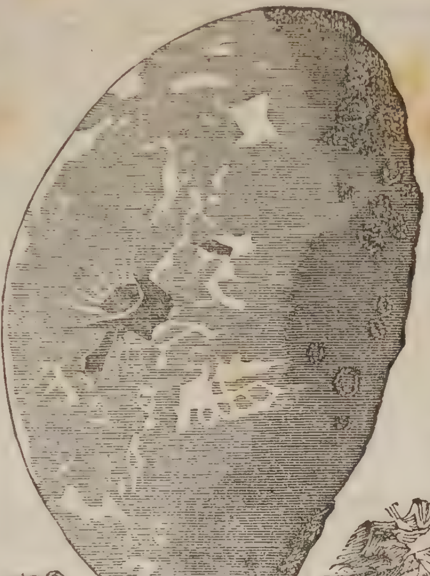

Fig. 85. (No. 1.)

Fig. 85. (No. 2.)

Whether there be any evidence of Volcanoes in the Moon.—From a consideration of the broken and irregular ground, and the deep caverns which appear in different parts of the moon's surface, several astronomers were led to conjecture that such irregularities were of volcanic origin. These conjectures were supposed to be confirmed by the appearance of certain luminous points, which were occasionally seen on the dark part of the moon. During the annular eclipse of the sun on the 24th of June, 1778, Don Ulloa perceived, near the north-west limb of the moon, a bright white spot, which he imagined to be the light of the sun shining through an opening in the moon. This phenomenon continued about a minute and a quarter, and was noticed by three different observers. Beccaria observed a similar spot in 1772. M. Bode, of Berlin, M. de Villeneuve, M. Nouet, Captain Kater, and several others, at different times observed similar phenomena, some of which had the appearance of a small nebula, or a star of the sixth magnitude, upon the dark part of the lunar disc. Sir W. Herschel, in 1787, observed similar phenomena, which he ascribes to the eruption of volcanoes. The following is an extract from his account of those phenomena: "April 19, 1787, 10*h.* 36*m.* I perceive three volcanoes in different places of the dark part of the new moon. Two of them are already nearly extinct, or otherwise in a state of going to break out; the third shows an eruption of fire or luminous matter. The distance of the crater from the northern limb of the moon is 3′ 57″; its light is much brighter than the nucleus of the comet which M. Mechain discovered at Paris on the 10th of this month." "April 20, 10*h.* The volcano burns with greater violence than last night; its diameter cannot be less than three seconds; and hence the shining or burning matter must be above three miles in diameter. The appearance resembles a small piece of burning charcoal when it is covered by a very thin coat of white ashes, and it has a degree of brightness about as strong as that with which such a coal would be seen to glow in faint daylight."

Such are some of the phenomena from which it has been concluded that volcanoes exist in the moon. That such appearances indicate the existence of fire or some species of luminosity on the lunar surface, is readily admitted; but they by no means prove that anything similar to terrestrial volcanoes exist in that orb. We err egregiously when we suppose that the arrangements of other worlds must be similar to those on our globe, especially when we perceive the surface of the moon arranged in a manner so very different from that of the earth. We have no right to conclude that burning mountains abound in the moon because these are the only large streams of fire that occasionally burst forth from certain points on our globe. For there are many other causes of which we are ignorant, and which may be peculiar to the moon, which may produce the occasional gleams or illuminations to which we allude. The conflagration of a large forest, such as happened a few years ago at Miramichi, the blazing of large tracts of burning heath, the illumination of a large town, or the conflagration of such a city as Moscow, would, in all probability, present to a spectator in the moon luminous specks such as those which astronomers have observed on the dark portion of the lunar orb. Such luminosities in the moon may possibly be of a phosphoric nature, or a mere display of some brilliant artificial scenery by the inhabitants of that planet. Schroeter is of opinion that most of these appearances are to be ascribed to the light reflected from the earth to the dark part of the moon's disc, which returns it from the tops of the mountains under various angles, and with different degrees of brightness; and from various observations I have made on the dark portion of the moon, when about two or three days old, and from the degree of brightness with which some of the small spots have frequently appeared, I am disposed to consider this opinion as highly probable.

The existence of volcanoes on our globe is scarcely to be considered as a part of its original constitution. Such appalling and destructive agents appear altogether inconsistent with the state of an innocent being formed after the Divine image; and, therefore, we have no reason to believe that they existed in the primitive age of the world, while man remained in his paradisiacal state, but began to operate only after the period of the universal deluge, when the primitive constitution of our globe was altered and deranged, and when earthquakes, storms, and tempests began, at the same time, to exert their destructive energies. They are thus to be considered as an evidence or indication that man is no longer in a state of moral perfection and that his habitation now corresponds with his character as a sinner. To suppose, therefore, that such destructive agents exist in the moon, would be virtually to admit that the inhabitants of that planet are in the same depraved condition as the inhabitants of this world. The same thing may be said with regard to a pretended discovery which was announced some years ago, that "there are *fortifications* in the moon;" for, if such objects really existed, it would be a plain proof that the inhabitants were engaged in wars and contentions, and animated with the same diabolical principles of pride, ambition, and revenge, which have ravaged our globe and demoralized its inhabitants.

Whether there be Seas in the Moon is a question which has engaged the attention of astronomers, and which demands a few remarks. When we view the moon through a good telescope, we perceive a number of large dark spots, of different dimensions, some of which are visible to the naked eye. These spots, in the early observations of the moon with telescopes, were generally supposed to be large collections of water similar to our seas, and the names given them by Hevelius, such as *Mare Crisium*, *Mare Imbrium*, &c., are founded on this opinion. The general smoothness of these obscure regions, and the consideration that water reflects less light than the land, induced some astronomers to draw this conclusion. But there appears no solid ground for entertaining such an opinion; for, in the first place, when these dark spots are viewed with good telescopes, they are found to contain numbers of cavities, whose shadows are distinctly perceived falling within them, which can never happen in a sea or smooth liquid body; and beside, several insulated mountains, whose shadows are quite perceptible, are found here and there in these supposed seas. In the next place, when the boundary of light and darkness passes through these spots, it is not exactly a straight line or a regular curve, as it ought to be were those parts perfectly level like a sheet of water, but appears slightly jagged or uneven. I have inspected these spots hundreds of times, with powers of 150, 180, and 230 times, and in every instance, and in every stage of the moon's increase and decrease, gentle elevations and depressions were seen, similar to the wavings or inequalities which are perceived upon a plain or country generally level. There are scarcely any parts of these spots in which slight elevations may not be seen. In many of them the light and shade, indicating the inequality of surface, are quite perceptible; and in certain parts ridges nearly parallel, of slight elevation, with interjacent plains, are distinctly visible. These dark spots, therefore, must be considered as *extensive plains* diversified with gentle elevations and depressions, and consisting of substances calculated to reflect the light of the sun with a *less degree of intensity* than the other parts of the lunar surface. These plains are of different dimensions, from 40 or 50 to 700 miles in extent, and they occupy more than one-third of that hemisphere of the moon which is seen from the earth, and, consequently, will contain nearly three millions of square miles. As the moon, therefore, is diversified with mountains and cavities of forms altogether different from those of our globe, so the plains upon the surface of that orb are far more varied and extensive than the generality of plains which are found on the surface of the earth. It is a globe diversified with an immense variety of mountain-scenery, and, at the same time, abounding with plains and valleys of vast extent. But there appear to be no seas, oceans, or any *large* collections of water, though it is possible that small lakes or rivers may exist on certain parts of its surface. As we see only one side of the moon from the earth, we cannot tell what objects or arrangements may exist on its opposite hemisphere, though it is probable that that hemisphere does not differ *materially* in its scenery and arrangements from those which are seen on the side which is turned toward the earth.

Atmosphere of the Moon.—Whether the moon has an atmosphere, or body of air similar to that which surrounds the earth, has been a subject of dispute among astronomers. On the one side, the existence of such an atmosphere is denied, because the stars which disappear behind the body of the moon retain their full luster until they seem to touch its very edge, and then they vanish in a moment; which phenomenon, it is supposed, would not happen if the moon were encompassed with an atmosphere. On the other hand, it has been maintained that the phenomena frequently attending eclipses of the sun furnish arguments for the existence of a lunar atmosphere. It has been observed on different occasions that the moon in a solar eclipse was surrounded with a luminous ring, which was most brilliant on the side nearest the moon; that the sharp horns of the solar crescent have been seen blunted at their extremities during total darkness; that, preceding the emersion, a long narrow streak of dusky red light has been seen to color the western limb of the moon; and that the circular figure of Jupiter, Saturn, and the fixed stars has been seen changed into an elliptical one when they approached either the dark or the enlightened limb of the moon; all which circumstances are considered as indications of a lunar atmosphere. The celebrated M. Schroeter, of Lilienthal, made numerous observations in order to determine this question, and many respectable astronomers are of opinion that his observations clearly prove the existence of an atmosphere around the moon. He discovered near the moon's cusps a faint gray light of a pyramidal form, extending from both cusps into the dark hemisphere, which, being the moon's twilight, must necessarily arise from its atmosphere. It would be too tedious to detail all the observations of Schroeter on this point; but the following are the general conclusions: "That the inferior or more dense part of the moon's atmosphere is not more than 1500 English feet high; and that the hight of the atmosphere where it could affect the brightness of a fixed star, or inflect the solar rays, does not exceed 5742 feet," or little more than an English mile. A fixed star will pass over this space in less than two seconds of time; and if it emerge at a part of the moon's limb where there is a ridge of mountains, scarcely any obscuration can be perceptible.

On the whole, it appears most probable that the moon is surrounded with a fluid which serves the purpose of an atmosphere, although this atmosphere, as to its nature, composition, and refractive power, may be very different from the atmosphere which surrounds the earth. It forms no proof that the moon or any of the planets is destitute of an atmosphere because its constitution, its density, and its power of refracting the rays of light are different from ours. An atmosphere may surround a planetary body, and yet its parts be so fine and transparent that the rays of light from a star or any other body may pass through it without being in the least obscured or changing their direction. In our reasonings on this subject we too frequently proceed on the false principle that everything connected with other worlds must bear a resemblance to those on the earth. But as we have seen that the surface of the moon, in respect to its mountains, caverns, and plains, is very differently arranged from what appears on the landscape of our globe, so we have every reason to conclude that the atmosphere with which that orb may be surrounded is materially different in its constitution and properties from that body of air in which we move and breathe; and it is highly probable, from the diversity of arrangements which exists throughout the planetary system, that the atmospheres of all the planets are variously constructed, and have properties different from each other. Whatever may be the nature of the moon's atmosphere, it is evident that nothing similar to *clouds* exist in it, otherwise they would be quite perceptible by the telescope; and hence we may conclude that neither hail, snow, rain, nor tempests disturb its serenity; for all the parts uniformly present a clear, calm, and serene aspect, as if its inhabitants enjoyed a perpetual spring.

Magnitude of the Moon.—The distance of the moon from the earth is determined from its horizontal parallax; and this distance, compared with its *apparent* angular diameter, gives its *real* or linear diameter. The mean horizontal parallax is fifty-seven minutes, thirty-four seconds, and the mean apparent diameter thirty-one minutes, twenty-six seconds. From these *data* it is found that the real diameter of the moon is 2180 miles, which is little more than the one-fourth of the diameter of the earth. The real magnitude of the moon, therefore, is only about one-forty-ninth part of that of the earth. This is found by dividing the cube of the earth's diameter by the cube of the moon's, and the quotient will express the number of times that the bulk of the earth exceeds that of the moon; for the real bulk of globes is in proportion to the cubes of their diameters. Although the apparent size of the moon appears equal to that of the sun, yet the difference of their real bulk is very great, for it would require more than *sixty-three millions* of globes of the size of the moon to form a globe equal in magnitude to that of the sun. Its surface, notwithstanding, contains a very considerable area, comprising nearly 15,000,000 of square miles, or about one-third of the habitable parts of our globe; and were it as densely peopled as England, it would contain a population amounting to *four thousand two hundred millions,* which is more than five times the population of the earth; so that the moon, although it ranks among the smallest of the celestial bodies, may contain a population of intelligent beings far more numerous, and perhaps far more elevated in the scale of intellect, than the inhabitants of our globe.

Whether it may be possible to discover the inhabitants of the moon is a question which has been sometimes agitated. To such a question I have no hesitation in replying, that it is highly improbable that we shall ever obtain a direct view of any living beings connected with the moon by means of any telescopes which it is in the power of man to construct. The greatest magnifying power which has ever been applied, *with distinctness*, to the moon, does not much exceed a thousand times; that is, makes the objects in the moon appear a thousand times larger and nearer to the naked eye. But even a power of a thousand times represents the objects on the lunar surface at a distance of 240 miles, at which distance no living beings, although they were nearly of the size of a kraken, could be perceived. Even although we could apply a power of ten thousand times, lunar objects would still appear 24 miles distant; and at such a distance no animal, even of the size of an elephant or a whale, could be discerned. Beside, we ought to consider that we have only a *bird's-eye view* of the objects on the moon; and, consequently, supposing any beings resembling man to exist on that orb, we could only perceive the diameter of their heads, as an aeronaut does when he surveys the crowds beneath him from an elevated balloon. Nay, though it were possible to construct a telescope with a power of one hundred thousand times, which would cause the moon to appear as if only two and a half miles distant, it is doubtful if, even with such an instrument, living beings could be perceived. We ought also to consider that nature has set certain limits to the magnifying power of telescopes; for, although we could apply such powers as now stated to any telescope, the vapors and undulations of the atmosphere, and the diurnal motion of the earth, would interpose a barrier to distinct vision; and as the quantity of light is diminished in proportion to the magnifying power, the loss of light in such high powers would prevent the distinct perception of any object.

But although we can never hope to *see* any of the inhabitants of the moon by any instrument constructed by human ingenuity, yet we may be able *to trace the operations* of sentient or intelligent beings, or those *effects* which indicate the agency of living beings. A navigator who approaches within a certain distance of a small island, although he perceives no human beings upon it, can judge with certainty that it is inhabited if he perceive human habitations, villages, corn-fields, or traces of cultivation. In like manner, if we could perceive changes or operations in the moon which could be traced to the agency of intelligent beings, we should then obtain demonstrative evidence that such beings exist on that planet; and I have no doubt that it is possible to trace such operations. A telescope which magnifies 1200 times will enable us to perceive, *as a visible point* on the surface of the moon, an object whose diameter is only about 100 yards or 300 feet. Such an object is not larger than many of our public edifices; and, therefore, were any such edifices rearing in the moon, or were a town or city extending its boundaries, or were operations of this description carrying on in a district where no such edifices had previously been erected, such objects and operations might probably be detected by a minute inspection. Were a multitude of living creatures moving from place to place in a body, or were they encamping in an extensive plain like a large army, or like a tribe of Arabs in the desert, and afterward removing, it is possible that such movements might be traced by the difference of shade or color which such movements would produce. In order to detect such minute objects and operations, it would be requisite that the surface of the moon should be distributed among at least a hundred astronomers, each having a spot or two allotted him as the object of his more particular investigation, and that the observations be continued for a period of at least thirty or forty years, during which time certain changes would probably be perceived, arising either from physical causes or from the operations of living agents. But although no such changes should ever be detected, it would form no proof that the moon is destitute of inhabitants; for, in other worlds, intelligent beings may probably enjoy all the happiness congenial to their natures without those edifices or artificial accommodations which are requisite for man in this terrestrial abode. In reference to the subject under consideration, Dr. Olbers is fully of opinion "that the moon is inhabited by rational creatures, and that its surface is more or less covered with a vegetation not very dissimilar to that of our own earth." Gruithuisen maintains that he has discovered, by means of his large achromatic telescope, "great artificial works in the moon, erected by the lunarians." And lately, another foreign observer maintains, from actual observation, "that great edifices do exist in the moon." I am of opinion that all such announcements are premature and uncertain. Without calling in question the accuracy of the descriptions published by these astronomers, there is some reason to suspect that what they have taken for "edifices" and "artificial works" are only small portions of natural scenery, of which an immense variety, in every shape, is to be found on the surface of the moon. Future and more minute observations may, however, enable us to form a definite opinion on this subject.*

---

* A short time ago a *hoax* was attempted to be played off on the public in relation to this subject. An article entitled "Wonderful Discoveries in the Moon, by Sir John Herschel," was copied into most of the American, French, and British newspapers and other periodicals, and was likewise published in a separate pamphlet. It is not a little astonishing how easily the public is gulled by such extravagant descriptions as were contained in this pamphlet, and it shows the *ignorance* which still prevails among the great mass of the community in every country in relation to astronomy and optics, that such pretended discoveries should have been listened to even for a moment. For even some editors of newspapers treated the affair in a grave manner, and only expressed their *doubts* on the subject, plainly indicating that they had far less knowledge of the science of astronomy than many schoolboys now acquire. The title of the pamphlet was sufficient to convince any man of common understanding, who directed his attention for a moment to the subject, that the whole was a piece of deception; for it stated that "the object-glass weighed *seven tons*," and had "a magnifying power of 42,000 times." Now, supposing such a power had been used, the objects on the surface of the moon would still have appeared more than five miles and two-thirds distant; and how could an animal, even of the largest size, be seen at such a distance? Yet the writer of the pamphlet declares that animals such as sheep, and cranes, and small birds were not only distinguished, but the shape and color of their horns, eyes, beard, and the difference of sexes, were perceived. To perceive such objects it was requisite that they should have been brought within six yards instead of six miles. The author might have rendered his description more consistent by putting a power of 300,000 times upon his imaginary telescope, since he had every power at his command, so as to have brought the objects, at least, within the distance of a mile. The author of this deception, I understand, is a young man in the city of New York, who makes some pretensions to scientific acquirements, and he may perhaps be disposed to congratulate himself on the success of his experiment on the public. But it ought to be remembered that all such attempts to deceive are violations of the laws of the Creator, who is the "God of truth," and who requires "truth in the inward parts;" and, therefore, they who willfully and deliberately contrive such impositions ought to be ranked in the class of liars and deceivers. The "Law of *Truth*" ought never for a moment to be sported with. On the universal observance of this law depends the happiness of the whole intelligent system and the foundations of the throne of the Eternal. The greatest part of the evils which have afflicted our world have risen from a violation of this law, and were it to be *universally* violated, the inhabitants of all worlds would be thrown into a state of confusion and misery, and creation transformed into a chaos. Beside, the propagation of such deceptions is evidently injurious to the interests of science. For when untutored minds and the mass of the community detect such impositions, they are apt to call in question the *real* discoveries of science, as if they were only attempts to impose on their credulity. It is to be hoped that the author of the deception to which I have adverted, as he advances in years and in wisdom, will perceive the folly and immorality of such conduct.

It has sometimes been a subject of speculation whether it might be possible, by any symbols, to correspond with the inhabitants of the moon. "Gruithuisen, in a conversation with the great continental astronomer Gauss, after describing the regular figures he had discovered in the moon, spoke of the possibility of a correspondence with the lunar inhabitants. He brought to Gauss' recollection the idea he had communicated many years ago to Zimmerman. Gauss answered, that the plan of erecting a geometrical figure on the plains of Siberia corresponded with his opinion, because, according to his view, a correspondence with the inhabitants of the moon could only be begun by means of such mathematical contemplations and ideas which we and they must have in common."* Were the inhabitants of the moon to recognize such a figure, erected on an immense scale, as a signal of correspondence, they might perhaps erect a similar one in reply. But it is questionable whether the intention of such a signal would be recognized; and our terrestrial sovereigns are too much engaged in plunder and warfare to think of spending their revenues in so costly an experiment; and, therefore, it is likely that, for ages to come, we shall remain in ignorance of the genius of the lunar inhabitants. Schemes, however, far more foolish and preposterous than the above have been contrived and acted upon in every age of the world. The millions which are now wasting in the pursuits of mad ambition and destructive warfare might, with far greater propriety, be expended in constructing a large triangle or ellipsis, of many miles in extent, in Siberia or any other country, which might at the same time accommodate thousands of inhabitants who are now roaming the deserts like the beasts of the forest.

Whatever may be the arrangements of the moon or the genius of its inhabitants, we know that it forms a most beautiful and beneficial appendage to our globe. When the sun has descended below the western horizon, the moon lights up her lamp in the azure firmament, and diffuses a mild radiance over the landscape of the world. She pours her luster on spacious cities and lofty mountains, glittering on the ocean, the lakes, and rivers, and opening a prospect wide as the eye can reach, which would otherwise be involved in the deepest gloom. As the son of Sirach has observed, "She is the beauty of heaven, the glory of the stars, an ornament giving light in the high places of the Lord." She cheers the traveler in his journeys, the shepherd while tending his fleecy charge, and the mariner while conducting his vessel at midnight through the boisterous ocean. She returns to us, during night, a portion of the solar light which we had lost, and diffuses a brilliancy far superior to that which we derive from all the stars of heaven. If we intend to prosecute our journeys after the sun has left our hemisphere, the moon, in her increase, serves as a magnificent lamp to guide our footsteps. If we wish to commence our progress at an early hour in the morning, the moon, in her decrease, diffuses a mild radiance in the east, and enables us to anticipate the dawn; and if we choose to defer our journey until the period of full moon, this celestial lamp enables us to enjoy, as it were, an uninterrupted day of twenty-four hours long. By this means we can either avoid the burning heats of summer, or dispatch such business as may be inexpedient during the light of day. While the apparent revolution of the sun marks out the year and the course of the seasons, the revolution of the moon round the heavens marks out our months; and, by regularly changing its figure at the four quarters of its course, subdivides the month into periods of weeks; and thus exhibits to all the nations of the earth a "watchlight" or signal, which every seven days presents a form entirely new, for marking out the shorter periods of duration. By its nearness to the earth, and the consequent increase of its gravitating power, it produces currents in the atmosphere, which direct the course of the winds and purify the aerial fluid from noxious exhalations; it raises the waters of the ocean, and produces the regular returns of ebb and flow, by which the liquid element is preserved from filth and putrefaction. It extends its sway even over the human frame, and our health and disorders are sometimes partially dependent on its influence. Even its eclipses, and those it produces of the sun, are not without their use. They tend to arouse mankind to the study of astronomy and the wonders of the firmament; they serve to confirm the deductions of chronology, to direct the navigator, and to settle the geographical positions of towns and countries; they assist the astronomer in his celestial investigations, and exhibit an agreeable variety of phenomena in the scenery of the heavens. In short, there are terrestrial scenes presented in moonlight, which, in point of solemnity, grandeur, and picturesque beauty, far surpass in interest, to a poetic imagination, all the brilliancy and splendors of noonday. Hence, in all ages, a moonlight scene has been regarded, by all ranks of men, with feelings of joy and sentiments of admiration. The following description of Homer, translated into English verse by Mr. Pope, has been esteemed one of the finest night-pieces in poetry:

> "Behold the moon, refulgent lamp of night,
> O'er heaven's clear azure spread her sacred light,
> When not a breath disturbs the deep serene,
> And not a cloud o'ercasts the solemn scene;
> Around her throne the vivid planets roll,
> And stars unnumbered gild the glowing pole;
> O'er the dark trees a yellower verdure shed,
> And tip with silver every mountain's head;
> Then shine the vales; the rocks in prospect rise,
> A flood of glory bursts from all the skies.
> The conscious swains, rejoicing in the sight,
> Eye the blue vault, and bless the useful light."

Without the light of the moon, the inhabitants of the polar regions would be for weeks and months immersed in darkness. But the moon, like a kindly visitant, returns at short intervals in the absence of the sun, and cheers them with her beams for days and weeks together. So that, in this nocturnal luminary, as in all the other arrangements of nature, we behold a display of the paternal care and beneficence of that Almighty Being who ordained "the moon and stars to rule the night," as an evidence of his superabundant goodness, and of "his mercy, which endureth for ever."

II. ON THE SATELLITES OF JUPITER.

There are four moons or satellites attending the planet Jupiter, which revolve around it from west to east, according to the order of the signs, or in the same direction as the moon revolves round the earth and the planets round the sun. They are placed at different distances from the center of Jupiter; they revolve round it in different periods of time, and they accompany the planet in its twelve years' revolution round the sun, without deviating in the least in their distances from the planet, as the more immediate center of their motions. These bodies were discovered by Galileo, who first applied the telescope to celestial observations. Three of them were first seen on the night of the 7th of January, 1610, and were at first supposed to be telescopic stars; but by the observations of three or four subsequent evenings, he discovered them to be attendants on the planet Jupiter. On the 13th of the same month he saw the fourth satellite, and continued his observations until March 2, when he sent his drawings of them, and an account of his observations, to his patron, *Cosmo Medici*, Great Duke of Tuscany, in honor of whom he called them the *Medicean stars.* This discovery soon excited the attention of astronomers, and every one hastened with eagerness to view the new celestial wonders. The senators of Venice who were eminent for their learning, invited Galileo to come to the tower of St. Mark, and in their presence make a trial of his new instruments. He complied with their request, and in a fine night, neither cold nor cloudy, showed them with his instrument the new phenomena which had excited attention; the satellites of Jupiter, the crescent of Venus, the triple appearance of Saturn, and the inequalities on the surface of the moon, which many of the learned refused to admit, because they overthrew the system of the schools and the philosophical notions which had previously prevailed. At this conference with the Venetian senators Galileo demonstrated the truth of the Copernican system, and showed how all his discoveries had a tendency to prove that the earth is a moving body, and that the sun is the center of the planetary motions.

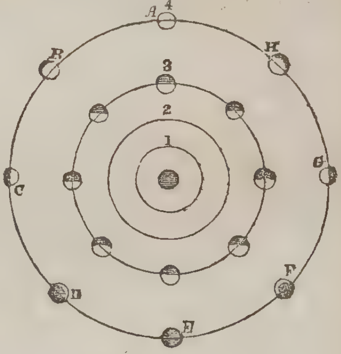
---

* Edinburgh New Philosophical Journal for October, 1826, p. 390.

The following are the respective distances of the satellites of Jupiter, in round numbers, and the periodic times in which they revolve around that planet. The mean distance of the first satellite from the center of Jupiter is 260,000 miles, or somewhat more than the distance of the moon from the earth; and it revolves around the planet in 1 day, 18 hours, 27½ minutes. The second satellite is distant 420,000 miles, and finishes its revolution in 3 days, 13 hours, 13⅔ minutes.—The third is distant 670,000 miles, and performs its revolution in 7 days, 3 hours, 42½ minutes. The fourth satellite is distant 1,180,000 miles, or more than four times the distance of the first, and requires 16 days, 16 hours, and 32 minutes to complete its revolution. These satellites suffer numerous eclipses in passing through the shadow of Jupiter, as our moon is eclipsed in passing through the shadow of the earth. But as their orbits are very little inclined to the orbit of Jupiter, their eclipses are much more frequent than those of our moon. The first three satellites are eclipsed every time they are in opposition to the sun. The first satellite is in opposition once in 42½ hours, and, consequently, suffers an eclipse about eighteen times every month. The second suffers eight or nine eclipses, and the third about four eclipses every month. But the fourth satellite frequently passes through its opposition without being involved in the shadow of Jupiter, and, consequently, its eclipses are less frequent than those of the other three, only a few of them happening in the course of a year. As those satellites are opaque globes like our moon—when they are in their inferior conjunction, or in a line between Jupiter and the sun—their bodies are interposed between the sun and certain parts of the disc of the planet, so as to cause an eclipse of the sun to those places over which their shadow passes. These eclipses, or the shadows of the satellites passing across the body of Jupiter, are perceived by powerful telescopes. Sometimes the satellites themselves may be seen crossing the disc like luminous spots; and sometimes the body of the planet interposes between our eye and the satellites, when they are said to suffer an *occultation.* It has been ascertained, by the calculations and investigations of La Place, *that the whole number of these moons can never be eclipsed at the same time,* and that scarcely ever more than two of them can be eclipsed at once.

The following diagram (Fig. 86), exhibits the system of Jupiter's satellites nearly in the proportion of their distances from the planet. The small circles on the orbit of the third satellite represent the enlightened side of the satellites turned toward the sun, and the dark side in an opposite direction. The enlightened side of every satellite is always very nearly turned toward the earth; but in their revolutions round Jupiter they present to that planet all the phases of the moon, as represented in the figures marked on the orbit of the fourth satellite. In the direction *A*, when in opposition to the sun, they appear like *full moons;* in the direction *B* they assume a *gibbous* phase; at *C* they appear like a *half moon;* at *D* like a *crescent;* at *E*, the dark side being turned toward the planet, the satellite becomes invisible; at *F*, *G*, and *H*, it again successively appears under a crescent, a half moon, and a gibbous phase. In the direction *A* the satellites are in opposition to the sun, as seen from Jupiter, at which time they pass through his shadow, and are eclipsed for the space of more than two hours, with the exception of the fourth, which sometimes passes the point of its opposition without falling into the shadow At *E* the shadow of the satellite passes across the disc of Jupiter, producing a solar eclipse to all those regions on his surface over which the shadow moves.

Fig. 86.



87

88

89

These satellites, when viewed from the earth, do not appear to revolve round Jupiter in the manner here represented, but seem to oscillate backward and forward nearly in a straight line. This is owing to our being nearly on a level with the plane of their orbits. When the earth is i one of the geocentric nodes of a satellite, the plane of its orbit passes through our eye, and therefore it appears to be a straight line, as *a b*, (Fig. 87), so that, in passing the half of its orbit which is most distant from the earth, it first seems to move from *b* to *c*, when it is hidden for some time by the planet, and then from *d* to *a*, the point of its greatest elongation; after which it seems to return again in the same line, passing between us and the disc of the planet, until it arrives at its greatest elongation at *b*. In every other situation of the earth, the orbit of a satellite appears as an ellipsis more or less oblong, as represented in Fig. 88. When it passes through its superior semicircle, or that which is more distant from the earth than Jupiter is, as *e*, *f*, *g*, its motion is *direct*, or according to the order of the signs; when it is in its inferior semicircle, nearer to us than Jupiter, as *h*, *i*, *k*, its apparent motion is in the opposite direction, or *retrograde*. Hence these satellites, as seen through a telescope, appear nearly in a straight line from the body of Jupiter, as represented in Fig. 89.

Magnitude of the Satellites.—These bodies, though invisible to the naked eye, are nevertheless of a considerable size. The following are their diameters in miles, as stated by Strüve. The first satellite is 2508 miles in diameter, which is considerably larger than our moon. The second is 2068 miles in diameter, or about the size of the moon. The third is 3377 miles in diameter, which is more than seven times the bulk of the moon.—The fourth is 2890 miles in diameter, or about three times the bulk of the moon; so that the whole of Jupiter's satellites are equal to nearly thirteen of our moons.* The superficial contents of the first satellite is 19,760,865 square miles; of the second, 13,435,442; of the third, 35,827,211; and of the fourth, 26,238,957 square miles. The number of square miles on all the satellites, is therefore, 95,262,475, or more than ninety-five millions of square miles, which is about double the quantity of surface on all the habitable parts of our globe. At the rate of 280 inhabitants to every square mile, these satellites would, therefore be capable of containing a population of 26,673 *millions*, which is thirty-three times greater than the population of the earth.

The satellites of Jupiter may be seen with a telescope magnifying about thirty times; but in order to perceive their eclipses with advantage, a power of one hundred or one hundred and fifty times is requisite. When the brilliancy of the satellites is examined at different times, it appears to undergo a considerable change. By comparing the mutual positions of the satellites with the times when they acquire their maximum of light, Sir W. Herschel concluded that, like the moon, they all turned round their axis in the same time that they performed their revolution round Jupiter. The same conclusion had been deduced by former astronomers in reference to the fourth satellite. This satellite was sometimes observed to take but half the usual time in its entrance on the disc of Jupiter or its exit from it, which was supposed to be owing to its having a dark spot upon it that covered half its diameter; and, by observing the period of its variations, it was concluded that it had a rotation round its axis. These circumstances form a presumptive proof that the surface of these satellites, like our moon, are diversified with objects of different descriptions, and with varieties of light and shade. Cassini suspected the first satellite to have an atmosphere, because the shadow of it could not be seen, when he was sure it should have been, upon the disc of Jupiter, if it had not been shortened by its atmosphere, as in the case in respect to the shadow of the earth in lunar eclipses.

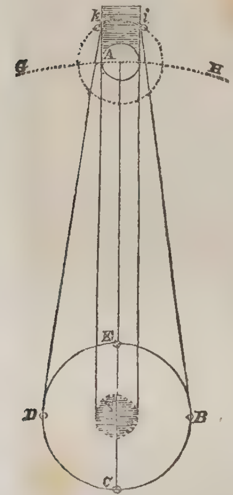
From what has been stated respecting the motions, magnitudes and eclipses of these satellites, it is evident they will present a most diversified and sublime scenery in the firmament of Jupiter.—The first satellite moves along a circumference of 1,633,632 miles in the space of 42½ hours, at the rate of 38,440 miles an hour, which is a motion sixteen times more rapid than that of the moon in its circuit round the earth. During this short period it presents to Jupiter all the appearances of a new moon, crescent, half moon, gibbous phase, and full moon, both in the increase and decrease; so that, in the course of twenty-one hours, it passes through all the phases which our moon exhibits to us; beside suffering an eclipse in passing through the shadow of the planet, and producing either a partial or total eclipse of the sun to certain regions of Jupiter on which its shadow falls. The rapidity of its motion through the heavens will also be very striking; as it will move through the whole hemisphere of the heavens in the course of twenty-one hours, beside its daily apparent motion, in consequence of the diurnal rotation of Jupiter. The other three satellites will exhibit similar phenomena, but in different periods of time. Sometimes two or three of these moons, and sometimes all the four, will be seen shining in the firmament at the same time; one like a crescent, one like a half-moon, and another in all its splendor as a full enlightened hemisphere; one entering into an eclipse, another emerging from it; one interposing between the planet and the sun, and for a short time intercepting his rays; one advancing from the eastern horizon, and another setting in the west; one satellite causing the shadows of objects on Jupiter to be thrown in one direction, and another satellite causing them to be projected in another, or in an opposite direction; while the rapid motions of these bodies among the fixed stars will be strikingly perceptible. Eclipses of the satellites and of the sun will be almost an every-day phenomenon, and occultations of the fixed stars will be so frequent and regular as to serve as an accurate measure of time.

The eclipses of Jupiter's satellites afford signals of considerable use for determining the longitude of places on the earth. For this purpose tables of these eclipses, and of the times at which the satellites pass across the disc of Jupiter or behind his body, are calculated and inserted in the nautical and other almanacs. These tables are adapted to the meridian of the Royal Observatory at Greenwich; and by a proper use of them, in connection with observations of the eclipses, the true meridian, or the distance of a place east or west from Greenwich, may be ascertained. For example: suppose, on the 27th of December, 1837, the immersion of Jupiter's first satellite be observed to happen, in an unknown meridian, at 15 hours, 23 minutes, 10 seconds, I find by the tables that this immersion will happen at Greenwich at 13 hours, 34 minutes, 50 seconds of the same day. The difference of the time is 1 hour, 48 minutes, 20 seconds, which, being converted into degrees of the equator (allowing 15 degrees for an hour), will make 27 degrees, 5 minutes, which is the longitude of the place of observation. This longitude is *east* of Greenwich, because the time of observation was *in advance* of the time at the British observatory. Had the time of observation been behind that of Greenwich, for example, at 13 hours, 4 minutes, 50 seconds, the place must then have been 7½ degrees west of the Royal Observatory. *Before* Jupiter's opposition to the sun, or when he passes the meridian in the morning, the shadow is situated to the *west* of the planet, and the *immersions* happen on that side; but *after* the opposition the *emersions* happen to the *east*. These eclipses cannot be observed with advantage unless Jupiter be eight degrees *above*, and the sun at least eight degrees *below* the horizon.

---

*Former astronomers reckoned the bulk of the satellites larger than the dimensions here stated. Cassini and Maraldi reckoned the diameter of the third satellite to be one-eighteenth of the diameter of Jupiter, and, consequently, nearly 5000 miles in diameter; and the first and second to be one-twentieth of Jupiter's diameter, or about 4450 miles; which estimation would make the magnitudes of these bodies much larger than stated by Struve.

Fig. 90.



The eclipses of Jupiter's moons first suggested the idea of *the motion of light*. As the orbit of the earth is concentric with that of Jupiter, the mutual distance of these two bodies is continually varying. In the following figure let *S* represent the sun; *B*, *C*, *D*, *E*, the orbit of the earth; and *G*, *H*, a portion of the orbit of Jupiter. It is evident that when the earth is at *E* and Jupiter at *A*, the earth will be the semidiameter of its orbit nearer Jupiter than when it is at *B* or *D;* and when at *C* it will be the whole diameter of its orbit, or 190,000,000 of miles farther from Jupiter than when it is at *E*. Now if light were instantaneous, the satellite *i*, to a spectator at *B*, would appear to enter into Jupiter's shadow, *k i*, at the same moment of time as to another spectator at *E*. But, from numerous observations, it was found, that when the earth was at *E*, the immersion of the satellite into the shadow happened sooner by eight minutes and a quarter than when the earth was at *B*, and sixteen minutes and a half sooner than when the earth was at *C*. It was therefore concluded that light is not instantaneous, but requires a certain space of time to pass from one region of the universe to another, and that the time it takes in passing from the sun to the earth, or across the semidiameter of the earth's orbit, is eight minutes and a quarter, or at the rate of 192,000 miles every second, which is more than ten hundred thousand times swifter than a cannon ball the moment it is projected from the mouth of the cannon; and therefore it is the swiftest movement with which we are acquainted in nature. It follows that, if the sun was annihilated, we should see him for eight minutes afterward; and if he were again created, it would be eight minutes before his light would be perceived. The motion of light deduced from the eclipses of Jupiter's satellites has been confirmed by Dr. Bradley's discovery of the *aberration of light* produced by the annual motion of the earth, from which it appears that the light from the fixed stars moves with about the same velocity as the light of the sun.

III. ON THE SATELLITES OF SATURN.

Saturn is surrounded with no less than seven satellites, which revolve around him, at different distances, in a manner similar to those of Jupiter. As they are more difficult to be perceived than the satellites of Jupiter, owing to the great distance of Saturn from the earth, none of them were discovered until the telescope was considerably improved; and more than a century intervened after the first five satellites until the sixth and seventh were detected. As was to be supposed, the larger satellites were first discovered. In the year 1665, about forty-five years after the invention of the telescope, M. Huygens, a celebrated Dutch mathematician and astronomer, discovered the fourth satellite, which is the largest, with a telescope twelve feet long. Four of the others were discovered by Cassini; the fifth in 1671, which is next in brightness to the fourth; the third in December, 1672; and the first and second in the month of March, 1684. These four satellites were first observed by common refracting telescopes of 100 and 136 feet in length; but, after being acquainted with them, he could see them all, in a clear sky, with a tube of thirty-four feet. The sixth and seventh satellites, were discovered by Sir W. Herschel in August, 1789, soon after his large forty feet reflecting telescope was completed. These are nearer to Saturn than the other five; but, to avoid confusion they are named in the order of their discovery. The following is the order of the satellites in respect of their distance from Saturn:

Seventh.	Sixth.	First.	Second.	Third.	Fourth.	Fifth.
1	2	3	4	5	6	7

The motions and distances of these bodies have not been so accurately ascertained as those of Jupiter. The following statement contains a near approximation of their periods and distances. The seventh satellite, or that nearest to Saturn, is distant, 120,000 miles from the center of the planet, about 80,000 from its surface, and only about 18,000 miles beyond the edge of the outer ring. It moves round the planet in twenty-two hours, thirty-seven minutes, a circuit of 377,000 miles, at the rate of 16,755 miles an hour. The sixth satellite, or the second from Saturn, is distant 150,000 miles, and finishes its revolution in one day, eight hours, fifty-three minutes. The first of the old satellites, or the third from Saturn, finishes its periodical revolution in one day, twenty-one hours, eighteen minutes, at the distance of 190,000 miles. The second (or fourth from Saturn), in two days, seventeen hours, forty four and three-quarter minutes, at the distance of 243,000 miles. The third (fifth from Saturn), in four days, twelve hours, fifty-five minutes, at the distance of 340,000 miles. The fourth (sixth from Saturn), in fifteen days, twenty-two hours fifty-one minutes, at the distance of 788,000 miles. The fifth (seventh from Saturn), in seventy-nine days, seven hours, and fifty-four and a half minutes, at the distance of 2,297,000 miles.

The orbits of the six inner satellites are inclined about thirty degrees to the plane of Saturn's orbit, and lie almost exactly in the plane of the rings, and therefore they appear to move in ellipses similar to the ellipses of the rings. But the orbit of the fifth or outer satellite, makes an angle with the plane of Saturn's orbit of 24 degrees, 45 minutes. These satellites, having their orbits inclined at so great angles to Saturn, cannot cross the body of that planet, or go behind it, or pass through its shadow, as Jupiter's satellites do, except on rare occasions, and hence they very seldom suffer eclipses or occultations. The only time when eclipses happen is near the periods when the ring is seen edgewise. The fifth or most distant satellite is sometimes invisible in the eastern part of its orbit, which is supposed to arise from one part of the satellite being less luminous than the rest. Sir W. Herschel observed this satellite through all the variations of its light, and concluded, as Cassini had done before, that it turned round its axis like our moon, in the same time that it performed its revolution round Saturn. In consequence of this rotation, the obscure part of its disc is turned toward the earth when in the part of its orbit east of Saturn; and the luminous portion of its surface is turned to the earth and becomes visible while it passes through the western part of its course.

Of these satellites the two innermost are the smallest and the most difficult to be perceived.—They have never been discerned but with most powerful telescopes, and then under peculiar circumstances. At the time of the disappearance of the ring, "they have been seen threading, like beads, the most infinitely thin fiber of light to which it is then reduced, and, for a short time, advancing off it at either end." Few astronomers beside Sir W. Herschel and his son have been able to detect these small bodies. The celebrated Schroeter and Dr. Harding, on the 17th, 20th, 21st, and 27th of February, 1798, obtained several views of the sixth satellite (the second from Saturn) by means of a reflecting telescope 13 feet long, carrying a power of 288. Their observations fully confirmed the accuracy of Sir W. Herschel's statement of the period of its revolution. The first and second satellites (third and fourth from Saturn) are the next smallest; the third (fifth from Saturn) is greater than the first and second; the fourth (sixth from Saturn) the most conspicuous and the most distant satellite, according to Sir John Herschel, is by far the largest, although it is not so conspicuous in one part of its orbit. In order to see any of the satellites of this planet, a good telescope, with a power of at least 70 or 80 times, is requisite, and with such a power only the two outermost satellites will be perceived. To perceive all the five old satellites requires a power of at least 200 times, and a considerable quantity of light.

Magnitude of Saturn's Satellites.—The precise bulk of these satellites has not yet been accurately determined. Sir John Herschel estimates the most distant satellite, which he thinks the largest, as not much inferior in size to the planet Mars, which is 4200 miles in diameter. The fourth satellite, which is the most conspicuous, cannot be supposed to be much inferior to it in bulk.—But as the precise dimensions of most of the inner satellites cannot be estimated with accuracy, we shall not, perhaps, exceed the dimensions of these bodies if we suppose for the whole a general average of 3000 miles diameter for each. On this assumption, the surface of each satellite will contain 28,274,400 of square miles, which is nearly double the area of our moon. The area of all the seven satellites will therefore amount to 197,920,800 square miles, which is four times the quantity of surface on all the habitable parts of the earth. At the rate of 280 inhabitants to the square mile, these satellites would therefore contain 55,417,824,000, or more than *fifty-five thousand millions* of inhabitants, which is sixty-nine times the population of our globe.

These satellites will present a beautiful and variegated appearance in the firmament of Saturn; the nearest satellite, being only 80,000 miles from the *surface* of the planet, which is only the one-third of the distance of the moon from the earth, will exhibit a very large and splendid appearance. Supposing it to be only about the diameter of our moon, it will present a surface nearly nine times larger than the moon does to us; and in the course of twenty-two and a half hours will exhibit all the phases of a crescent, half moon, full moon, &c., which the moon presents to us in the course of a month; so that almost every hour its phase will be sensibly changed, and its motion round the heavens will appear exceedingly rapid. While, in consequence of the diurnal rotation of Saturn, it will appear to move from east to west, it will also be seen moving with a rapid velocity among the stars in a contrary direction, and will pass over a whole hemisphere of the heavens in the course of eleven hours. The next satellite in order from Saturn, being only 110,000 miles from its surface, will also present a splendid appearance, much larger than our moon, and will exhibit all the phases of the moon in the course of sixteen hours. All the other satellites will exhibit somewhat similar phenomena, but in different periods of time. They will appear, when viewed from the surface of Saturn, of different sizes; some of them nine times larger than the moon appears to us, some three times, some double the size, and it is probable that even the most distant satellites will appear nearly as large as our moon, so that a most beautiful and sublime variety of celestial phenomena will be presented to a spectator in the heavens of Saturn, beside the diversified aspects of the rings to which we formerly adverted, all displaying the infinite grandeur and beneficence of the Creator.

IV. ON THE SATELLITES OF URANUS.

This planet is attended by six satellites, all of which were discovered by Sir W. Herschel, to whom we owe the discovery of the planet itself. The second and fourth satellites were detected in January, 1787, about six years after the planet was discovered; the other four were discovered several years afterward, but their distances, and periodical revolutions have not been so accurately ascertained as those of the two first discovered.

The *first* of these satellites, or the nearest to Uranus, completes its sidereal revolution in 5 days, 21 hours, and 25 minutes, at the distance of 224,000 miles from the center of the planet. The *second* in 8 days, 17 hours, at the distance of 291,000 miles. The *third* in 10 days, 23 hours, at the distance of 340,000 miles. The *fourth* in 13 days, 11 hours, at the distance of 390,000 miles. The *fifth* in 38 days, 1 hour, 48 minutes, at the distance of 777,000 miles. The *sixth* in 107 days, 16 hours, 40 minutes, at the distance of 1,556,000 miles.

These bodies present to our view some remarkable and unexpected peculiarities. Contrary to the analogy of the whole planetary system, *the planes of their orbits are nearly perpendicular to the ecliptic*, being inclined no less than 79 degrees to that plane. Their motions in these orbits are likewise found to be *retrograde*, so that, instead of advancing from west to east round Uranus, as all the other planets and satellites do, they move in the opposite direction. Their orbits are quite circular, or very nearly so, and they do not appear to have undergone any material change of inclination since the period of their discovery. "These anomalous peculiarities," says Sir John Herschel, "seem to occur at the extreme limits of the system, as if to prepare us for further departure from all its analogies in other systems which may yet be disclosed to us" in the remoter regions of space.

The satellites of Uranus are the most difficult objects to perceive of any within the boundary of the planetary system, excepting the two interior satellites of Saturn; and therefore few observers, excepting Sir William and Sir John Herschel, have obtained a view of them. Their magnitudes, of course, have never been precisely determined; but there is every reason to believe that they are, on an average, as large as the satellites of Saturn, if not larger, otherwise they could not be perceived at the immense distance at which they are placed from our globe. Supposing them, on an average, to be 3000 miles in diameter—and they can scarcely be conceived to be less—the surfaces of all the six satellites will contain 169,646,400 square miles, or about 3½ times the area of all the habitable portions of the earth; and which, at the rate formerly stated, would afford scope for a population of 47,500,992,000, or above forty-seven thousand millions, which is about sixty times the present number of the inhabitants of the earth.

The satellites of Uranus seldom suffer eclipses; but as the plane in which they move must pass twice in the year through the sun, there may be eclipses of them at those times; but they can be seen only when the planet is near its opposition. Some eclipses were visible in 1799 and 1818, when they appeared to ascend through the shadow of the planet in a direction almost perpendicular to the plane of its orbit. It is probable that this planet is attended with more satellites than those which have yet been discovered. It is not unlikely that two satellites, at least, revolve between the body of the planet and the first satellite; for the third satellite of Saturn is not nearly so far distant from the surface of that planet as the first satellite of Uranus is from its center. But as the inner satellites may be supposed to be the smallest, and yet present as large a surface to the planet as the exterior ones, it is probable that, on account of their diminutive size, they may never be detected. It is likewise not improbable that two satellites may exist in the large spaces which intervene between the orbits of the fourth and fifth, and the fifth and sixth satellites. All these satellites will not only pour a flood of light on this distant planet, but will exhibit a splendid and variegated appearance in its nocturnal firmament.

The satellites of Jupiter, Saturn, and Uranus, of which we have given a brief description in the preceding pages, form, as it were, so many distinct planetary systems in connection with the great system of the sun. The same laws of motion and gravitation which apply to the primary planets are also applicable to the secondary planets or moons. The squares of their periodical times are in proportion to the cubes of their distances. They are subject to the attraction of their primaries, as all the primary planets are attracted by the sun; and as the sun, in all probability, is carried round a distant center along with all his attendants, so the satellites are carried round the sun along with their respective planets; partly by the influence of these planets, and partly by the attractive power of the great central luminary.—Each of these secondary systems forms a system by itself, far more grand and extensive than the whole planetary system was conceived to be in former times. Even the system of Saturn itself, including its rings and satellites, contains a mass of matter more than a thousand times larger than the earth and moon. The system of Jupiter comprises a mass of matter nearly fifteen hundred times the size of these two bodies; and even that of Uranus is more than eighty times the dimensions of our terrestrial system.

CHAPTER V.

ON THE PERFECTIONS OF THE DEITY, AS DISPLAYED IN THE PLANETARY SYSTEM.

All the works of nature speak of their Author in language which can scarcely be misunderstood. They proclaim the existence of an original, uncreated Cause, of an eternal Power and Intelligence, and of a supreme agency which no created being can control. "The heavens," in a particular manner, "declare the glory of God, and the firmament showeth forth his handiwork."—When we consider the heavenly orbs in their size, their distance, the rapidity of their motions, and the regularity and harmony with which they perform their respective revolutions, it is obvious to the least attentive observer that such bodies could not have formed themselves, or have arranged their motions, their periods, and their laws in the beautiful order in which we now behold them. Motion of every kind supposes a moving power. As matter could not make itself, so neither can it set itself in motion. Its motion must commence from a power exterior to itself, and that power must correspond in energy to the *effect* produced. In the planetary system we find bodies a thousand times larger than the earth moving with a velocity sixty times greater than a cannon ball, and carrying along with them in their train other expansive globes in the same swift career. Such motions could only proceed from a power which is beyond calculation or human comprehension; and such a power can only reside in an uncreated, self-existent, and independent Intelligence. The *continuance* of such motions must likewise depend upon the incessant agency of the same Almighty Being, either directly, or through the medium of such subordinate agents as he is pleased to appoint for the accomplishment of his designs. In this respect the laws of motion, of attraction, gravitation, electricity, and other powers, are so many agents, under the direction and control of the Almighty, for carrying forward the plans of his physical and moral government of the universe.

The study of astronomy ought always to have in view as its ultimate object, to trace the Divine perfections as displayed in the phenomena of the heavens. For, as our poet Milton expresses it, "Heaven is as the book of God before us set, wherein to read his wondrous works." There is no scene we can contemplate in which the attributes of the Divinity are so magnificently displayed. It is in the heavens alone that we perceive a sensible evidence of the *infinity* of his perfections, of the grandeur of his operations, and of the immeasurable extent of his universal dominions. Even the planetary system, small as it is in comparison of the whole extent of creation, contains within it wonders of creating Omnipotence and skill which almost overpower the human faculties, and demonstrate the "eternal power and godhead" of Him who at first brought it into existence. To consider astronomy merely as a secular branch of knowledge, which improves navigation, and gives scope to the mathematician's skill, and to overlook the demonstrations it affords of the invisible Divinity, would be to sink this noble study far below its native dignity, and to throw into the shade the most illustrious manifestations of the glories of the Eternal mind.

When we contemplate the stupendous globes of which the planetary system is composed, and the astonishing velocity with which they run their destined rounds, we cannot but be struck with an impressive idea of the POWER of the Deity; of the incomprehensible ENERGIES of the Eternal Mind that first launched them into existence. What are all the efforts of puny man as displayed in the machinery he has set in motion, and in the most magnificent structures he has reared, in comparison with worlds a thousand times larger than this earthly ball, and with *forces* which impel them in their courses at the rate of thirty thousand, and even a hundred thousand miles an hour! The mind is overpowered and bewildered when it contemplates such august and magnificent operations. Man, with all his imaginary pomp and greatness, appears, on comparison, as a mere microscopic animalcula, yea, as "less than nothing and vanity;" and such displays of the omnipotence of Jehovah are intended to bring down the "lofty looks of men," and to stain the pride of all human grandeur, "that no flesh should glory in his presence." Without materials, and without the aid of instruments or machinery, the foundations of the planetary system were laid, and all its arrangements completed. "He only *spake* and it was done;" he only gave the *command*, and mighty worlds started into existence and ran their spacious rounds. "By the word of the Lord were the heavens made, and all the host of them by the breath of His mouth." That Almighty Being who, by a single volition, could produce such stupendous effects, must be capable of effecting what far transcends our limited conceptions. His agency must be universal and uncontrollable, and no created being can ever hope to frustrate the purposes of his will or counteract the designs of his moral government. Whatever he has promised will be performed; whatever he has predicted by his inspired messengers must assuredly be accomplished. "For the kingdom is the Lord's, He is the Governor among the nations," and all events, and the movements of all intelligent beings, are subject to his sovereign control. "Though the mountains should be carried into the midst of the seas, and the earth reel to and fro like a drunkard;" yea, though this spacious globe should be wrapped in flames, and "all that it inherits be dissolved," yet that power which brought into existence the planetary worlds, and has supported them in their rapid career for thousands of years, can cause "new heavens and a new earth, wherein dwelleth righteousness," to arise out of its ruins, and to remain in undiminished beauty and splendor.

"The heavens," says an inspired writer, "declare the glory of the Lord, and there is no speech nor language where their voice is not heard." Even the pagan nations were impressed with the power of a supreme intelligence from a contemplation of the nocturnal firmament. "When we behold the heavens," says Cicero, "when we contemplate the celestial bodies, can we fail of conviction? Must we not acknowledge that there is a Divinity, a perfect being, a ruling intelligence that governs, a God who is everywhere, and directs all by his power? Any one who doubts this may as well deny that there is a sun that enlightens us." Plato, when alluding to the motions of the sun and planets, exclaims, "How is it possible for such prodigious masses to be carried round for so long a period by any natural cause? for which reason I assert God to be the great and first cause, and that it is impossible that it should be otherwise."

A very slight view of the planetary system is sufficient to impress our minds with an overpowering sense of the *grandeur* and *omnipotence* of the Deity. In one part of it we behold a globe fourteen hundred times larger than our world flying through the depths of space, and carrying along with it a retinue of revolving worlds in its swift career. In a more distant region of this system we behold another globe, of nearly the same size, surrounded by two magnificent rings, which would inclose 500 worlds as large as ours, winging its flight through the regions of immensity, and conveying along with it seven planetary bodies larger than our moon, and the stupendous arches with which it is encircled, over a circumference of five thousand seven hundred millions of miles. Were we to suppose ourselves placed on the nearest satellite of this planet, and were the satellite supposed to be at rest, we should behold a scene of grandeur altogether overwhelming; a globe filling a great portion of the visible heavens, encircled by its immense rings, and surrounded by its moons, each moving in its distinct sphere and around its axis, and all at the same time flying before us in perfect harmony with the velocity of 22,000 miles an hour. Such a scene would far transcend everything we now behold from our terrestrial sphere, and all the conceptions we can possibly form of motion, of sublimity, and grandeur. Contemplating such an assemblage of magnificent objects moving through the ethereal regions with such astonishing velocity, we would feel the full force of the sentiments of inspiration: "THE LORD GOD OMNIPOTENT REIGNETH. His power is irresistible; His greatness is unsearchable; wonderful things doth he which we cannot comprehend." The *motions* of the bodies which compose this system convey an impressive idea of the agency and the energies of Omnipotence. One of these bodies, eighty times larger than the earth, and the slowest moving orb in the system, is found to move through its expansive orbit at the rate of fifteen thousand miles an hour; another at twenty-nine thousand miles in the same period, although it is more than a thousand times the size of our globe; another at the rate of eighty thousand miles; and a fourth with a velocity of more than a hundred thousand miles every hour, or thirty miles during every beat of our pulse. The mechanical forces requisite to produce such motions surpass the mathematician's skill to estimate or the power of numbers to express. Such astonishing velocities, in bodies of so stupendous a magnitude, though incomprehensible and overwhelming to our limited faculties, exhibit a most convincing demonstration of the existence of an agency and a power which no created beings can ever counteract, and which no limits can control. Above all, the central body of this system presents to our view an object which is altogether overpowering to human intellects, and of which, in our present state, we shall never be able to form an adequate conception. A luminous globe, thirteen hundred thousand times larger than our world, and five hundred times more capacious than all the planets, satellites, and comets taken together, and this body revolving round its axis and through the regions of space, extending its influences to the remotest spaces of the system, and retaining by its attractive power all the planets in their orbits, is an object which the limited faculties of the human mind, however improved, can never grasp, in all its magnitude and relations, so as to form a full and comprehensive idea of its magnificence. But it displays in a most astonishing manner the GRANDEUR of Him who launched it into existence, and lighted it up "by the breath of his mouth;" and it exhibits to all intelligences a demonstration of his "eternal power and godhead." So that, although there were no bodies existing in the universe but those of the planetary system, they would afford an evidence of a *power* to which no limits can be assigned; a POWER which is infinite, universal, and uncontrollable.

The planetary system likewise exhibits a display of the *wisdom and intelligence* of the Deity. If it is an evidence of wisdom in an artist that he has arranged all the parts of a machine, and proportioned the movements of its different wheels and pinions so as exactly to accomplish the end intended, then the arrangement of the planetary system affords a bright display of "the manifold wisdom of God." In the *center* of this system is placed the great source of light and heat; and from no other point could those solar emanations be propagated, in an equable and uniform manner, to the worlds which roll around it. Had the sun been placed at a remote distance from the center, or near one of the planetary orbits, the planets in one part of their course would have been scorched with the most intense heat, and in another part would have been subjected to all the rigors of excessive cold; their motions would have been deranged, and their present constitution destroyed. The enormous bulk of this central body was likewise requisite to diffuse light and attractive influence throughout every part of the system. The diurnal *rotations* of the planets evince the same wisdom and intelligence. Were these bodies destitute of diurnal motions, one-half of their surface would be parched with perpetual day, and the other half involved in the gloom of a perpetual night. To the inhabitants of one hemisphere the sun would never appear, and to the inhabitants of the other the stars would be invisible; and those expansive regions of the universe, where the magnificence of God is so strikingly displayed, would be forever vailed from their view. The *permanency* of the axes on which the planets revolve was likewise necessary, in order to the stability of the system and the comfort of its inhabitants; and so we find that their poles point invariably in the same direction or to the same points of the heavens, with only a slight variation scarcely perceptible until after the lapse of centuries. As the planets are of a spheroidal figure, had the direction of their axes been liable to frequent and sudden changes, the most alarming and disastrous catastrophes might have ensued. In such a globe as ours, the shifting of its axis might change the equatorial parts of the earth into the polar, or the polar into the equatorial, to the utter destruction of those plants and animals which are not capable of interchanging their situations. Such a change would likewise cause the seas to abandon their former positions, and to rush to the new equator; the consequence of which would be, that the greater part of the men and animals with which it is now peopled would be again overwhelmed in a general deluge, and the habitable earth reduced to a cheerless desert. But all such disasters are prevented by the permanent position of the axis of our globe and of the other planets during every part of their annual revolutions, as fixed and determined by Him who is "wonderful in counsel and excellent in working."

The same wisdom is conspicuous in so *nicely balancing and proportioning the magnitudes, motions, and distances of the planetary orbs.* We find that the larger planets move in orbits most remote from the smaller planets and from the center of the system. If the great planets Jupiter and Saturn had moved in lower spheres and at no great distance from the smaller, their attractive force would have had a much more powerful influence than it now has in disturbing the planetary motions, and might have introduced considerable confusion into the system. But, while they revolve at so great distances from all the inferior planets, their influence is inconsiderable, and the slight perturbations they produce are not permanent, but *periodical;* they come to a limit, and then go back again to the same point as before. Again, *the law of gravitation,* by which the planets are directed in their motions, is also an evidence of Divine intelligence. The law is found to act reciprocally as the square of the distance; that is, at double the distance it has one-fourth, and at triple the distance one-ninth of the force; at one-half the distance it has four times, and at one-third the distance it has nine times the strength or influence. Now it could easily be shown, that a law directly opposite to this, or even differing materially from it, would not only derange the harmony of the system, but might be attended with the most disastrous consequences. If, for instance, a planet as large and as remote as Saturn had attracted the earth in proportion to the quantity of matter it contains, and, at the same time, *in any proportion to its distance;* in other words, had its attractive power been greater the farther it was removed from us, it would have dragged our globe out of its course, deranged its motions, and, in all probability, deprived us of the security we now possess, and of all the prospects and enjoyments which depend upon its equable and harmonious movements. There is no contrivance in the system more wonderful than the *rings* of Saturn. That these rings should be separated thirty thousand miles from the body of the planet; that they should, notwithstanding, accompany the planet in its revolution round the sun, preserving invariably the same distance from it; that they should revolve round the planet every ten hours, at the immense velocity of more than a thousand miles in a minute; and that they should never fly off to the distant regions of space, nor fall down upon the planet, are circumstances which require adjustments far more intricate and exquisite than we can conceive, and demonstrate that the almighty contriver of that stupendous appendage to the globe of Saturn is "great in counsel and mighty in operation." Yet these adjustments, in whatever they may consist, have been completely effected. For this planet has been flying through the regions of space in a regular curve for thousands of years, and the system of its satellites and rings still remains permanent and unimpaired as at its first creation.

An evidence of wisdom may likewise be perceived in the *distance* at which each planet is placed from the great central body of the system. In the case of our own globe, its distance from the sun is so adjusted as to correspond to the density of the earth and waters, to the temper and constitution of the bodies of men and other animals, and to the general state of all things here below. The quantity of light which the central luminary diffuses around us is exactly adapted to the structure of our eyes, to the width of their pupils, and the nervous sensibility of the retina. The heat it produces, by its action on the *caloric* connected with our globe, is of such a temperature as is exactly suited to the nature of the soil and to the constitution of the animal and vegetable tribes. It is placed at such a distance as to enlighten and warm us, and not so near as to dazzle us with its splendor or scorch us with its excessive heat; but to cheer all the tribes of living beings, and to nourish the soil with its kindly warmth. Were the earth removed fifty millions of miles farther from the sun, everything around us would be frozen up, and we should be perpetually shivering amid all the rigors of excessive cold. Were it placed as much nearer, the waters of the rivers and the ocean would be transformed into vapor; the earth would be hardened into an impenetrable crust; the process of vegetation would cease; and all the orders of animated beings would faint under the excessive splendor of the solar beams. There can be no doubt that the distances of the other planets are likewise adapted to the nature of the substances of which they are composed and the constitution of their inhabitants. We find that the *densities* of these bodies *decrease* in proportion to their distance from the sun; and it is highly probable that this is one reason, among others, why they are placed at different distances, and are thus adapted to the greater or less degree of influence which the central luminary may produce on their surfaces.

The *figures* of the planetary bodies likewise indicate contrivance and intelligence. They are all either of a spherical or spheroidal form, and this figure is evidently the best adapted to a habitable world. It is the most *capacious* of all forms, and contains the greatest quantity of area in the least possible space. It is the best adapted to motion, both annual and diurnal, every part of the surface being nearly at the same distance from the center of gravity and motion. Without this figure there could have been no comfortable and regular alternations of day and night in our world as we now enjoy, and the light of the sun and the mass of waters could not have been equably distributed. Had the earth been of a cubical, prismatic, or pentagonal form, or of any other angular figure, some parts would have been comparatively near the center of gravity, and others hundreds or thousands of miles farther from it; certain countries would have been exposed to furious tempests, which would have overturned and destroyed every object, while others would have been stifled for want of currents and agitation in the air; one part would have been overwhelmed with water, and another entirely destitute of the liquid element; one part might have enjoyed the benign influence of the sun, while another might have been within the shadow of elevations a hundred miles high, and in regions of insufferable cold. In short, while one country might have resembled a paradise, others would have been transformed into a chaos, where nothing was to be seen but barrenness and hideous desolation; but the globular figure which the Creator has given to our world prevents all such inconveniences and evils, and secures to us all the advantages we enjoy from the equable distribution of light and gravity, of the waters of our seas and rivers, and of the winds and motions of the atmosphere; and arrangements similar or analogous are enjoyed by all the other planetary worlds, in consequence of the globular figure which has been impressed upon them.

The same Divine Wisdom is displayed throughout the solar system *in the nice adjustment of the projectile velocity to the attractive power.* The natural tendency of all motion, impressed by a single force, is to make the body move in a *straight line.* The projectile force originally given to the planets, if not counteracted, would carry them away from the sun, in right lines, through the regions of infinite space. On the other hand, had the planets been acted upon solely by an attractive power proceeding from the center, they would have moved with an increased velocity toward that center, and, in a short time, have fallen upon the body of the sun. Now the Divine Intelligence strikingly appears in nicely proportioning and balancing these two powers, so as to make the planets describe orbits nearly circular. If these powers had not been accurately adjusted, the whole system would have run into confusion. For, were the velocity of any planet double to what would make it move in a circle or ellipse, it would rush from its sphere through the regions of immensity, and never again return to its former orbit. Or, should half its velocity be taken away, the planet would descend obliquely toward the sun until it became four times nearer him than before, and then ascend to its former place; and by ascending and descending alternately, would describe a very eccentric orbit, and would feel the influence of the solar light and power sixteen times greater in one part of its course than in another; which would prevent such a globe as ours, and probably all the planetary bodies, from being habitable worlds. But, in this respect, every part of celestial mechanism is adjusted with the nicest skill, and the whole system appears a scene of beauty, order, and stability worthy of the intelligence of Him "who hath established the world by his wisdom, and stretched out the heavens by his understanding." And as the power of gravitation was first impressed upon matter by the hand of the Creator, so its continued action is every moment dependent on his sovereign will. Were its influence to be suspended, the whole system would immediately dissolve and run into confusion. The centrifugal force of the planets, in whirling round their axes, would shatter them into pieces and dissipate their parts throughout the circumambient spaces; every portion of matter would fly in straight lines, according as the projectile force chanced to direct at the moment this power was suspended; and the regions of infinite space, instead of presenting a prospect of beauty and order, would become a scene of derangement, overspread with the wrecks of all the globes in the universe; so that the order and stability of universal nature entirely depends upon the will and the omnipotence of the Deity in sustaining in constant action the power of universal gravitation. Were it his pleasure that the material world should be dissolved and its inhabitants destroyed, he has only to interpose his Almighty fiat, and proclaim, "Let the power of attraction be suspended," and the vast universe would soon be unhinged and return to its original chaos.

In short, the depth of the Divine Wisdom might have been illustrated from the constant proportion between the times of the periodical revolutions of all the planets, primary and secondary, and the cubes of their mean distances; from the constancy and regularity of their motions, that, amid so immense a variety of moving masses, all should observe their due bounds and keep their appointed paths, to answer the great ends of their creation; from the exactness with which they run their destined rounds, finishing their circuits with so much accuracy as not to deviate from the periods of their revolutions a single minute in a hundred years; from the *distances* of the several planets from the sun, compared with their respective *densities;* from their velocities in their orbits compared with their distances from the central luminary; from the wonderful simplicity of the laws on which so much beauty, harmony, and enjoyment depend; and from various other considerations, all which would tend to demonstrate that He who framed the planetary system is "the only wise God," whose "understanding is infinite," and the depth of whose intelligence is "past finding out."

From what we have now stated, we may see what a beautiful and divine fabric the solar system exhibits. Like all the arrangements of Infinite Wisdom its foundations are plain and simple, but its superstructure is wonderful and diversified.—The causes which produce the effects are few, but the phenomena are innumerable. While the ends to be accomplished are numerous and various, the means are the fewest that could possibly bring the design into effect. What a striking contrast is presented between the works of Omnipotence as they really exist, and the bungling schemes of the ancient astronomers? who, with all their cycles, epicycles, concentric and eccentric circles, their deferents, and solid crystalline spheres, could never account for the motions of the planetary orbs, nor explain their phenomena. The plans of the Almighty, both in the material world and in his moral government, are quite unlike the circumscribed and complex schemes of man. Like himself, they are magnificent and stupendous, and yet accomplished by means apparently weak and simple. All his works are demonstrations, not only of his existence, but of his inscrutable wisdom and superintending providence. As the accomplishments of every workman are known from the work which he executes, so the operations of the Deity evince his supreme agency and his boundless perfections. What being less than infinite could have arranged the solar system, and launched from his hand the huge masses of the planetary worlds? What mathematician could so nicely calculate their distances and arrange their motions? Or what mechanic so accurately contrive their figures, adjust their movements, or balance their projectile force with the power of gravitation? None but He whose power is supreme and irresistible, whose agency is universal, and whose wisdom is unsearchable.

In the last place, the planetary system exhibits a display of the GOODNESS of the Creator and of his superintending care. The goodness of God is that perfection of his nature by which he delights to communicate happiness to every order of his creatures. Now all the movements and arrangements of the planetary bodies are so ordered and directed as to act in subserviency to the happiness of sentient and intelligent beings. This is evidently the grand design of all the wise contrivances to which we have adverted. The spherical figure given to all the planets for the regular distribution of the waters of the seas and rivers, and of the currents of the atmosphere; their rotation on their axes, to produce the alternate succession of day and night; the situation of the sun in the center of the system, for the equable distribution of light and heat to surrounding planets; and an apparatus of rings and moons, to reflect a mild radiance in the absence of the sun, are contrivances which can only have a respect to the comfort and convenience of animated beings; for they can serve no purpose to mere inert matter devoid of life and intelligence, and the Creator, so far as we know, never employs *means* without a corresponding end in view. In our world, the utility of these arrangements, in order to our happiness, is obvious to the least reflecting mind. Without light our globe would be little else than a gloomy prison; for it is this that cheers the heart of man, and unvails to our view the beauties and sublimities of creation; and had the earth no rotation, and were the sun continually shining on the same hemisphere, the temperate zones as well as the equatorial regions would be parched with a perpetual day, the moisture of the soil evaporated, the earth hardened, vegetables deprived of nourishment, the functions of the atmosphere deranged, and numerous other inconveniences would ensue, from which we are now protected by the existing arrangements of nature; and as such contrivances are essential to the comfort of the inhabitants of the earth, so we have every reason to conclude that these and all the additional arrangements connected with other planets are intended to promote the enjoyment of the different orders of sensitive and intelligent existence with which they are peopled.

As the object of the wise contrivances of the Deity is the communication of happiness, it would be inconsistent with every rational view we can take of his wisdom and intelligence not to admit that *the same end* is kept in view *in every part of his dominions*, however far removed from the sphere of our immediate contemplation, and though we are not permitted, in the mean time, to inspect the minute details connected with the economy of other worlds; for the Creator must always be considered as consistent with himself, as acting on the same eternal and immutable principles at all times, and throughout every department of his empire. He cannot be supposed to devise means in order to accomplish important ends in relation to our world, while in other regions of creation he devises means *for no end at all.* To suppose, for a moment, such a thing possible, would be highly derogatory to the Divine character, and would confound all our ideas of the harmony and consistency of the attributes of him who is "the only wise God." We have, therefore, the highest reason to conclude, that not only this earth, but the whole of the planetary system, is a scene of *divine benevolence;* for it displays to our view a number of magnificent globes, with special contrivances and arrangements, all fitted to be the abodes of intelligent beings, and to contribute to their enjoyment. Every provision has been made to supply them with that *light* which unfolds the beauties of nature and the glories of the firmament. All the arrangements for its equable distribution have been effected, and several wonderful modes unknown in our world have been contrived for alleviating their darkness in the absence of the sun, all which contrivances are, doubtless, accompanied with many others which lie beyond the range of our conception, and which our remote distance prevents us from contemplating. In proportion, then, as the other planets exceed the earth in size, in a similar proportion, we may conceive, is the extent of that theater on which the Divine goodness is displayed. If this "earth is full of the goodness of the Lord," if the benevolence of the Creator has distributed unnumbered comforts among every order of creatures here below, what must be the exuberance of his bounty, and the overflowing streams of felicity enjoyed in worlds which contain thousands of times the population of our globe! If a world which has been partly deranged by the sin of its inhabitants abounds with so many pleasures, what numerous sources of happiness must abound, and what ecstatic joys must be felt in those worlds where mortal evil has never entered, where diseases and death are unknown, and where the inhabitants bask perpetually in the regions of immortality! Were we permitted to take a nearer view of the enjoyments of some of those worlds, were we to behold the magnificent scenery with which they are encircled, the riches of Divine munificence which appear on every hand, the inhabitants adorned with the beauties of moral perfection, and every society cemented by the bond of universal love, and displaying the virtues of angelic natures, it is highly probable that all the enjoyments of this terrestrial sphere would appear only "as the drop of a bucket and the small dust of the balance," and as unworthy of our regard in comparison of the overflowing fountains of bliss which enrich the regions and gladden the society of the celestial worlds. In this point of view what a glorious and *amiable* being does the eternal Jehovah appear! "God is love." This is his name and his memorial in all generations and throughout all worlds. Supremely happy in himself and independent of all his creatures, his grand design in forming and arranging so many worlds could only be to display the riches of his beneficence, and to impart felicity, in all its diversified forms, to countless orders of intelligent beings, and to every rank of perceptive existence. And how *extensive* his goodness is, not only throughout the planetary system, but over all the regions of universal nature, it is impossible for the tongues of men or angels to declare, or the highest powers of intelligence to conceive. But of this we are certain, that "Jehovah is good to all;" that "his bounty is great above the heavens;" and that "his tender mercies are over all his works."

CHAPTER VI.

SUMMARY VIEW OF THE MAGNITUDE OF THE PLANETARY SYSTEM.

Having, in the preceding pages, given a brief description of the principal facts and phenomena connected with the solar system, and offered a few reflections suggested by the subject, it may not be inexpedient to place before the reader a summary view of the magnitude of the bodies belonging to this system, as compared with the population and magnitude of the globe on which we live. In this summary statement I shall chiefly attend to the *area* or superficial contents of the different planets, which is the only accurate view we can take of their magnitudes, when we compare them with each other as habitable worlds. The population of the different globes is estimated, as in the preceding descriptions, at the rate of 280 inhabitants to a square mile, which is the rate of population in England, and yet this country is by no means overstocked with inhabitants, but could contain, perhaps, double its present population.

	Square Miles.	Population.	Solid Contents.
Mercury	32,000,000	8,960,000,000	17,157,324,800
Venus	191,134,944	53,500,000,000	248,475,427,200
Mars	55,417,824	15,500,000,000	38,792,000,000
Vesta	229,000	64,000,000	10,035,000
Juno	6,380,000	1,786,000,000	1,515,250,000
Ceres	8,285,580	2,319,962,400	2,242,630,320
Pallas	14,000,000	4,000,000,000	4,900,000,000
Jupiter	24,884,000,000	6,967,520,000,000	368,283,200,000,000
Saturn	19,600,000,000	5,488,000,000,000	261,326,800,000,000
Saturn's outer ring	9,058,803,600	8,141,963,826,080	1,442,518,261,800
Inner ring	19,791,561,636		
Edges of the rings	228,077,000		
Uranus	3,848,460,000	1,077,568,800,000	22,437,804,620,000
The Moon	15,000,000	4,200,000,000	5,455,000,000
Jupiter's satellites	95,000,000	26,673,000,000	45,693,970,126
Saturn's satellites	197,920,800	55,417,824,000	98,960,400,000
Uranus's satellites	169,646,400	47,500,992,000	84,823,200,000
Amount	78,195,916,784	21,894,974,404,480	654,038,348,119,246

From the above statement, the real magnitude of all the moving bodies connected with the solar system may at once be perceived. If we wish to ascertain what proportion these magnitudes bear to the amplitude of our own globe, we have only to divide the different amounts stated at the bottom of the table by the area, solidity, or population of the earth. The amount of area, or the superficial contents of all the planets, primary and secondary, is 78,195,916,784; or above *seventy-eight thousand millions* of square miles. If this sum be divided by 197,000,000, the number of square miles on the surface of our globe, the quotient will be 397; showing that the surfaces of these globes are 397 times more expansive than the whole surface of the terraqueous globe; or, in other words, that they contain an amplitude of space for animated beings equal to nearly *four hundred worlds* such as ours. If we divide the same amount by 49,000,000, the number of square miles in the habitable parts of the earth, the quotient will be 1595; showing that the surface of all the planets contains a space equal to one thousand five hundred and ninety-five times the area of all the continents and islands of our globe. If the amount of population which the planets might contain, namely, 21,894,974,404,480, or nearly *twenty-two billions*, be divided by 800,000,000, the population of the earth, the quotient will be 27,368; which shows that the planetary globes could contain a population more than twenty-seven thousand times the population of our globe; in other words, if peopled in the proportion of England, they are equivalent to twenty-seven thousand worlds such as ours in its present state of population. The amount of the third column expresses the number of solid miles comprised in all the planets, which is 654,038,348,119,246, or more than *six hundred and fifty-four billions*. If this number be divided by 263,000,000,000, the number of cubical miles in the eart the quotient will be 2483, which shows that th solid bulk of the other planets is two thousand fou hundred and eighty-three times the bulk of our globe. Such is the immense magnitude of our planetary system, without taking into account either the sun or the hundreds of comets which have been observed to traverse the planetary regions.

Great, however, as these magnitudes are, they are far surpassed by that stupendous globe which occupies the center of the system. The surface of the sun contains 2, 432,800,000,000 square miles (nearly two and a half billions). If this sum be rightly divided by 197 millions, the number of square miles on the earth's surface, the quotient will be 12,350, which shows that the surface of the sun contains *twelve thousand three hundred and fifty* times the quantity of surface on our globe. If the same sum be divided by 78,195,916,784, the number of square miles in all the planets, the quotient will be 31, showing that the area of the surface of the sun is *thirty-one* times greater than the area of all the primary planets, with their rings and satellites. The solid contents of the sun amount to 356,818,739,200,000,000, or nearly three hundred and fifty-seven thousand billions of cubical miles, which number, if divided by 654,038,348,119,246, the number of solid miles in all the planets, will produce a quotient of 545, which shows that the sun is five hundred and forty-five times larger than all the planetary bodies taken together. Such is the vast and incomprehensible magnitude of this stupendous luminary, whose effulgence sheds day over a retinue of revolving worlds, and whose attractive energy controls their motions and preserves them all in one harmonious system. If this immense globe be flying through the regions of space at the rate of sixty thousand miles an hour, as is supposed, and carrying along with it all the planets of the system, it presents to the mind one of the most sublime and overwhelming ideas of motion, magnitude, and grandeur which the scenes of the universe can convey.

Fig. 92.

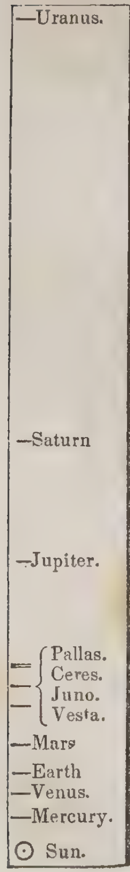


Fig. 91.

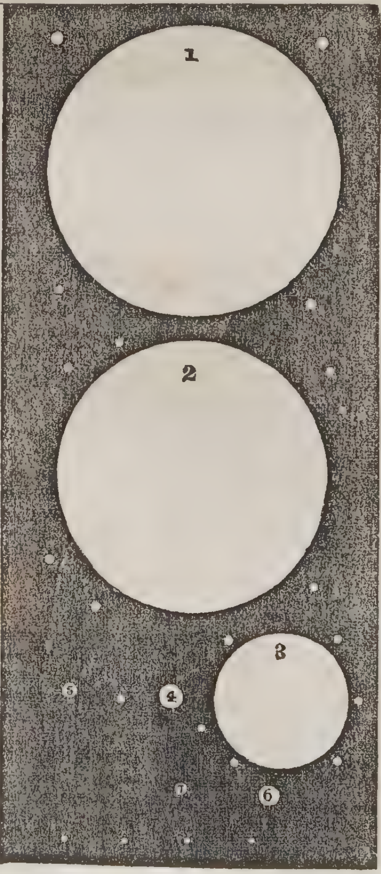

The comparative magnitudes of the different bodies in the system are represented to the eye in Fig. 91, where the circle at the top, No. 1, represents Jupiter; No. 2, Saturn; No. 3, Uranus; No. 4, the Earth; adjacent to which, on the left, is the Moon; No. 5, Mars; No. 6, Venus; and No. 7, Mercury. The four small circles at the bottom are the planets Vesta, Juno, Ceres, and Pallas, whose proportional sizes cannot be accurately represented. The other small circles connected with Jupiter, Saturn, and Uranus, are intended to represent the satellites of these planets, which in general may be estimated as considerably larger than our moon. These comparative magnitudes are only approximations to the truth; for it would require a large sheet were we to attempt delineating them with accuracy; but the figure will convey to the eye a *general* idea of the comparative bulks of these bodies, in so far as it can be conveyed by a comparison of their diameters;* but no representation on a plane surface can convey an idea of the *solid contents* of these globes as compared with each other. The reader will perceive the great disparity of globes, whose diameters do not differ very widely from each other, if he place a globe of twelve inches diameter beside one of eighteen inches diameter. Though these globes differ only six inches in their diameters, yet he will at once perceive that the eighteen-inch globe contains more than double the surface of the twelve-inch; and the *solid* space which it occupies contains $3\frac{3}{8}$ times the space occupied by the smaller globe. Were the sun to be represented in its proportional size to Jupiter and the other planets, it would fill a space *twenty inches in diameter*. On the same scale in which the planets are delineated, Saturn's ring would occupy a space four and a half inches in diameter. From these representations we may see how small a space our earth occupies in the planetary system, and what an inconsiderable appearance it presents in comparison with Jupiter, Saturn, and Uranus. Fig. 92 represents the *proportional distances* of the primary planets from the sun, from which it will be seen that Saturn, which was formerly considered the most distant planet, occupies nearly the middle of the system.

---

* The reader will find a comparative view of the distances and magnitudes of the planets, engraved on a very large sheet, in "Burritt's Geography of the Heavens" published at Hartford, North America.

In Fig. 93 is represented a comparative view of the earth and the rings of Saturn. The small circle at the right hand side represents the lineal proportion of our globe to those stupendous arches, so that the eye may easily perceive that hundreds of worlds such as ours could be inclosed within such expansive rings. Fig. 94 represents the proportion which the sun bears to the planet Jupiter, the largest planetary orb in the system. The large circle represents the sun, and the small circle Jupiter. If the earth were to be represented on the same scale, it would appear like a point scarcely perceptible. It is chiefly by the aid of such tangible representations that the mind can form any idea approximating to the reality of such magnitudes and proportions; and, after all its efforts, its views of such stupendous objects are exceedingly imperfect and obscure.

CHAPTER VII.

ON THE METHOD BY WHICH THE DISTANCES AND MAGNITUDES OF THE HEAVENLY BODIES ARE ASCERTAINED.

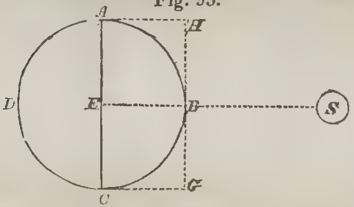
There is a degree of skepticism among a certain class of readers in regard to the conclusions which astronomers have deduced respecting the distances and magnitudes of the celestial bodies. They are apt to suspect that the results they have deduced are *merely conjectural*, and that it is impossible for human beings to arrive at anything like certainty, or even probability, in regard to distances so immensely great, and to magnitudes so far surpassing everything we see around us on this globe. Hence it is that the assertions of astronomers as to these points are apt to be called in question, or to be received with a certain degree of doubt and hesitation, as if they were beyond the limits of truth or probability. And hence such persons are anxious to inquire, "How can astronomers find out such things?" "Tell us by what methods they can measure the distances of the planets and determine their bulks?" Such questions, however, are more easily proposed than answered; not from any difficulty in stating the principles on which astronomers proceed in their investigations, but from the impossibility, in many instances, of conveying an idea of these principles to those who are ignorant of the elements of geometry and trigonometry. A very slight acquaintance with these branches of the mathematics, however, is sufficient to enable a person to understand the mode by which the distances of the heavenly bodies are determined; but a certain degree of information on such subjects is indispensably requisite, without which no satisfactory explanation can be communicated.

In offering a few remarks on this subject, I shall, in the first place, state certain considerations, level to the comprehension of the general reader, which prove that the celestial bodies are much more distant from the earth, and, consequently, much larger than they are generally supposed to be by the vulgar, and those who are ignorant of astronomical science; and, in the next place, shall give a brief view of the mathematical principles on which astronomers proceed in their calculations.

When a common observer views the heavens for the first time, previous to having received any information on the subject, he is apt to imagine that the sun, moon, and stars are placed in the canopy of the sky at nearly the same distance from the earth, and that this distance is only a little beyond the region of the clouds; for it is impossible, merely by the eye, to judge of the relative distances of such objects. Previous to experience, it is probable that we could form no correct idea of the relative distances of any objects whatever The young man who was born blind, and who was restored to sight at the age of thirteen, by an operation performed by Mr. Cheselden, could form no idea of the distances of the new objects presented to his visual organs. He supposed everything he saw touched his eyes, in the same manner as everything he felt touched his skin. An object of an inch diameter placed before his eyes, which concealed a house from his sight, appeared to him as large as the house. What he had judged to be round by the help of his hands he could not distinguish from what he had judged to be square; nor could he discern by his eyes whether what his hands had perceived to be above or below was really above or below; and it was not until after two months that he could distinguish pictures from solid bodies. In like manner we are apt to be deceived in our estimate of the distances of objects by the eye, particularly of those which appear in the concave of the heavens; and reason and reflection must supply the deficiency of our visual organs before we can arrive at any definite conclusions respecting objects so far beyond our reach.

That the heavenly bodies, particularly the sun, are much greater than they appear to the vulgar eye, may be proved by the following consideration: When the sun rises due east in the morning, his orb appears just as large as it does when he comes to the meridian at midday. Yet it can be shown that the sun, when he is on our meridian, is about 4000 miles nearer us than when he rose in the morning. This may be illustrated by the following figure.

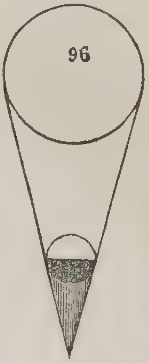
Fig. 95.

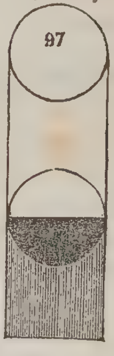


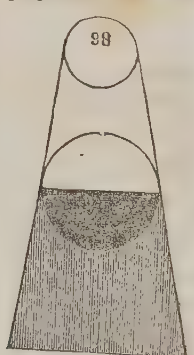
Let *A B C D* represent the earth, and *S* the sun at the point of his rising. Suppose the line *A E C* to represent the meridian of a certain place, and *A* or *E* the place of a spectator. When the sun, in his apparent diurnal motion, comes opposite the meridian *A C*, he is a whole semidiameter of the earth nearer the spectator at *E* than when he appeared in the eastern horizon. This semidiameter is represented by the lines *A H*, *E B*, *C G*, and is equal to 3965 miles. Now were the sun only four thousand miles distant from the earth, and consequently, eight thousand miles from us at his rising, he would be nearly four thousand miles nearer us when on the meridian than at his rising; and, consequently, he would appear twice the diameter, and four times as large in surface as he does at the time of his rising. But observation proves that there is no perceptible difference in his apparent magnitude in these different positions; therefore the sun must be much more distant from the earth than four thousand miles. If his distance were only 120,000 miles, his apparent diameter would appear 1-30th part broader when on the meridian than at the time of his rising, and the difference could easily be determined; but no such difference is perceptible; therefore the sun is still more distant than one hundred and twenty thousand miles.—And, as the *real* size of any body is in proportion to its distance, compared with its *apparent* size, the sun must, from this consideration alone, be *more* than 1200 miles in diameter, and must contain *more* than nine hundred millions of cubical miles. But how much greater his distance and magnitude are than what is now stated cannot be determined from such observations.

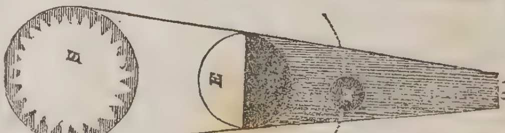
The same idea may be illustrated as follows: Suppose a spectator at Edinburgh, which may be represented by the point *A* (Fig. 95), and another at Capetown, in the southern extremity of Africa, about the time of our winter solstice, which position may be represented by the point *E*; both spectators might see the sun at the same moment, and he would appear exactly of the same size from both positions. Yet such spectators would be more than 4000 miles distant from each other in a *straight line*, and the observer at Capetown would be several thousands of miles nearer the sun than the one at Edinburgh. Now if the sun were only a few thousands of miles from the earth, he would appear of a very different magnitude to observers removed so far from each other which is contrary to fact. Consequently, the sun must be at a very great distance from the earth, and his real size proportionable to that distance. For experience proves that objects which are of great magnitude may appear comparatively small when removed from us to a great distance. The lofty vessel, as it recedes from the coast toward the ocean, gradually diminishes in its apparent size, until at length it appears as a scarcely distinguishable speck on the verge of the horizon; and the æronaut with his balloon, when they have ascended beyond the region of the clouds, appear only as a small dusky spot on the canopy of the sky, and sometimes entirely disappear.

The following argument, which is level to the comprehension of every reflecting mind, proves that the sun is larger than the whole globe of the earth, and that the moon is considerably less. Previous to the application of the argument to which I allude, it may be proper to illustrate the law of *shadows*. The law by which the shadows of globes are projected is as follows: When the luminous body is larger in diameter than the







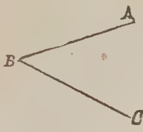


opaque body, the shadow which it projects converges to a point which is the vertex of a cone, as in Fig. 96. When the luminous and the opaque body are of an equal size, the shadow is cylindrical, and passes on from the opaque body to an indefinite extent, as represented in Fig. 97. When the luminous body is less than the opaque, the shadow extends in breadth beyond the opaque body, and grows broader and broader in proportion to its distance from the opaque globe, as in Fig. 98. This may be illustrated by holding a ball three or four inches in diameter opposite to a candle, when the shadow of the ball will be seen to be larger in diameter in proportion to the distance of the wall or screen on which the shadow is projected. Now it is well known, and will readily be admitted, that an eclipse of the moon is caused by the shadow of the earth falling upon the moon when the sun, earth, and moon are nearly in a straight line with respect to each other; and that an eclipse of the sun is caused by the shadow of the moon falling upon a certain portion of the earth. Let *S* (Fig. 99) represent the sun; *E*, the earth; and *M*, the moon, nearly in a straight line, which is the position of these three bodies in an eclipse of the moon. The shadow of the earth, at the distance of the moon, is found to be of a less diameter than the diameter of the earth. This is ascertained by the time which the moon takes in passing through the shadow. The real breadth of that shadow, at the moon's distance from the earth, is about 5900 miles, sometimes more and sometimes less, according as the moon is nearer to or farther from the earth; but the diameter of the earth is nearly 8000 miles; therefore the shadow of the earth gradually decreases in breadth in its progress through space, and, by calculation, it is found that it terminates in a point, as in Fig. 96, at the distance of about 850,000 miles. But when a luminous globe causes the shadow of an opaque globe to converge toward a point, as in Fig. 96, the luminous body must be larger in diameter than the opaque one. The sun is the luminous body which causes the earth to project a shadow on the moon; this shadow, at the moon, is less in breadth than the diameter of the earth; therefore it inevitably follows *that the sun is larger than the earth;* but how much larger cannot be determined from such considerations.

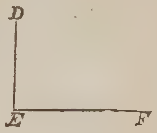
From the same premises it necessarily follows that the moon is *less* than the earth. For the moon is sometimes completely covered by the shadow of the earth, although this shadow is less than the earth's diameter, and not only so, but sometimes takes an hour or two in passing through the shadow. If the sun were only equal to the earth in size, the earth's shadow would be projected to an indefinite extent, and be always of the same breadth, and might sometimes eclipse the planet Mars when in opposition to the sun. If the sun were less than the earth, the shadow of the earth would increase in bulk the farther it extended through space (as represented in Fig. 98), and would eclipse the great planets Jupiter, Saturn, and Uranus, with all their moons, when they happened to be near their opposition to the sun; and in this case they would be deprived of the light of the sun for many days together. In such a case, too, the sun would sometimes be eclipsed to the earth by the planet Venus, when in its inferior conjunction with that luminary: an eclipse which might cause a total darkness of several hours' continuance. In short, if the sun were less than any one of the planets, the system would be thrown into confusion by the shadows of all these bodies increasing in proportion to their distance, and interrupting, periodically, for a length of time, the communications of light and heat. But as none of these things ever happen, it is evident that the sun is much larger than the whole terraqueous globe.

All that requires to be taken for granted by the unlearned reader in this argument is, that the earth is a globular body; that an eclipse of the moon is caused by the shadow of the earth falling upon that orb; and that the shadow of the earth, at the distance of the moon, is of less breadth than the earth's diameter. The first two positions will readily be admitted; and the third position, respecting the breadth of the earth's shadow, may be received on the ground of what has been above stated, and on the authority of astronomers. For, if they were ignorant of this circumstance, they could not calculate eclipses with so much accuracy as they do, and predict the precise moment of the beginning and end of a lunar eclipse

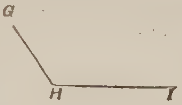
100



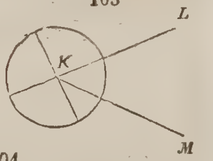
101



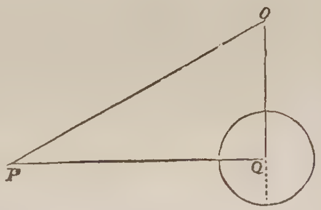
102



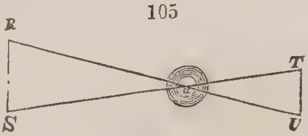
103



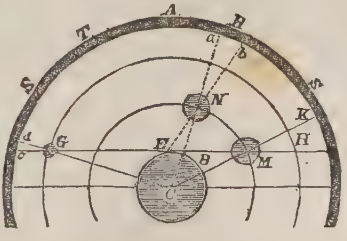
104



105



106



If, then, any individual is convinced, from the consideration above stated, that the sun must be much larger than the earth, he has advanced one step in his conceptions of the magnificence of the heavenly bodies, and may rest with confidence on the assertions of astronomers in reference to the *real* distances and magnitudes of these orbs, although he may not be acquainted with the mathematical principles and investigations on which their calculations proceed.

Before proceeding to the illustration of the trigonometrical principles on which astronomers proceed in determining the true distances of the heavenly bodies, it may be requisite, for the unlearned reader to give a description of the nature of angles and the mode by which they are measured. An angle is the opening between any two lines which touch each other in a point; and the width of the opening determines the extent of the angle, or the number of degrees or minutes it contains. Thus if we open a pair of compasses, the legs of which may be represented by *A B*, *B C*, Fig. 100, an angle is formed of different dimensions, according as the extremities of the legs are removed farther from or brought nearer to each other. If the legs are made to stand perpendicular to each other, as in Fig. 101, the angle is said to be a *right angle*, and contains ninety degrees, or the fourth part of a circle. The walls of a room generally stand at right angles to the floor. If the legs be separated more than a right angle, they form what is termed an *obtuse angle*, as in Fig. 102. When the angle is less than a right angle, it is called an *acute angle*, as in Fig. 100, and, consequently, contains a less number of degrees than ninety. All angles are measured by the arc of a circle described on the angular point; and every circle, whether great or small, is divided into 360 equal parts, called degrees. Thus, if I want to know the quantity of an angle at *K*, (Fig. 103) I place one point of the compasses at the angular point *K*, and describe the arc of a circle between the two sides *L K*, *K M*, and whatever number of degrees of a circle is contained between them is the quantity or measure of the angle. If, as in the present case, the angle contains the eighth part of a circle or half a right angle, it is said to be an angle of forty-five degrees. A *triangle* is a figure which contains three angles and three sides, as *O P Q*, Fig. 104. It is demonstrated by mathematicians, that the three angles of every triangle, whatever proportion these angles may bear to each other, are exactly equal to two right angles, or 180 degrees. Thus, in the triangle *O P Q*, the angle at *Q* is a right angle, or ninety degrees, and the other two angles, *O* and *P*, are together equal to ninety degrees; so that, if one of these angles be known, the other is found by subtracting the number of degrees in the known angle from ninety. Thus, if the angle at *P* be equal to thirty degrees, the angle at *O* will be equal to sixty degrees. Hence, if any two angles of a triangle be known, the third may be found by subtracting the sum of the two known angles from 180 degrees, the remainder will be the number of degrees in the third angle. All the triangles have their greatest sides opposite to their greatest angles; and if all the *angles* of the triangle be equal, the *sides* will also be equal to each other.

If any three of the six parts of a triangle be known (excepting the three angles) *all the other parts may be known from them.* Thus, if the side *P Q*, and the angles at *P* and *Q* be known, we can find the length of the sides *P O* and *O Q*. It is on this general principle that the distances and magnitudes of the heavenly bodies are determined.

In order to understand and apply this principle, it is necessary that we explain the nature of a *parallax*. A parallax denotes the change of the apparent place of any heavenly body, caused by being seen from different points of view. This may be illustrated by terrestrial objects as follows: Suppose a tree 40 or 50 yards distant from two spectators, who are 15 or 20 yards distant from each other; the one will perceive the tree in a line with certain objects near the horizon, which are considerably distant from those which appear in the direction of the tree, as viewed from the station occupied by the other spectator. The difference between the two points near the horizon where the tree appears to coincide to the two different spectators is the *parallax* of the object. If the tree were only 20 or 25 yards distant, the parallax would be twice as large; or, in other words, the points in the horizon where it was seen by the two spectators would be double the distance, as in the former case; and if the tree were two or three hundred yards distant, the parallax would be proportionably small. Or, suppose two persons sitting near each other at one side of a room, and a candle placed on a table in the middle of the room, the points on the opposite wall where the candle would appear to each of the two persons would be considerably distant from each other; and this distance may be called the parallax of the candle as viewed by the two observers. This may be illustrated by Fig. 105, where *R* and *S* may represent the positions of the observers; *a* the candle or tree; and *T* and *U* the points on the opposite wall or in the horizon where the candle or the tree appears to the respective observers. The observer at *R* sees the intermediate object at *U*; and the one at *S* sees it in the direction *S T*. The angle *R a S*, which is equal to the angle *T a U*, is called the angle of parallax, which is the difference of position in which the object is seen by the two observers. If, then, the distance between the observers *R S* be known, and the quantity of the angle *R a S*, the distance between the observers and the object can also be known by calculation.

Let us now apply this principle to the heavenly bodies. In Fig. 106 let the semicircle *S*, *T*, *A*, *R*, *S*, represent a section of the concave of the heavens; the middle circle, *E C*, the earth; *M*, the moon; *C*, the center of the earth; and *E H*, the sensible horizon of a spectator at *E*. It is evident that if the moon be viewed from the earth at the point *E*, she will be seen in the horizon at the point *H*; but were she viewed at the same time from *C*, the center of the earth, she would appear among the stars at the point *K*, in a more elevated position than when seen from the surface of the earth at *E*. The difference between these two apparent positions of the moon, or the angle *K M H*, is called the moon's *horizontal parallax*. Astronomers know from calculation in what point of the heavens the moon would appear as viewed from the earth's center; and they know from actual observation where she appears as viewed from the surface; and, therefore, can find the difference of the two positions, or the angle of parallax. This angle might likewise be found by supposing two spectators on different parts of the earth's surface viewing the moon at the same time. Suppose a spectator at *E*, who sees the moon in the horizon at *H*; and another observer, on the same meridian, at *B*, who sees her in his zenith at *K*; the parallax, as formerly, will be *K H*.

The parallax of a heavenly body decreases in proportion to its altitude above the horizon, and at the zenith (*A*) it is nothing, for the line from the center of the earth coincides with that from the surface, as *C E A* Thus the parallax of the moon at *N* (*a b*) is less than the horizontal parallax

K H; but from the parallax observed at any altitude, the horizontal parallax can be deduced; and it is from this parallax that the distance of the moon or any other heavenly body is determined. *The greater the distance of any body from the earth, the less is its parallax.* Thus the heavenly body *G*, which is farther from the earth than the moon, has a less parallax (*c d*) than that of the moon, *K H*.

Now the parallax of the moon being known, it is easy to find the distance of that orb from the earth; for in every triangle, if one side and two angles be known, the other angle and the other two sides can also be found. In the present case, we have a triangle *E M C*, in which the side *E C*, or the semidiameter of the earth, is known. The angle *M E C* is a right angle, or ninety degrees; and the parallatic angle *E M C* is supposed to be found by observation. From these *data*, by an easy trigonometrical calculation, the length of the side *C M*, or the distance of the moon from the center of the earth, can be determined with the utmost precision, provided the angle of parallax has been accurately ascertained.

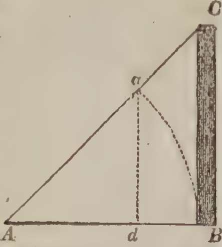
Before proceeding to illustrate by examples the method of calculating the distances of the heavenly bodies when the parallax is found, I shall present an example or two of the mode of computing the hights and distances of terrestrial objects, the principle on which we proceed being the same in both cases. Suppose it were required to find the hight of the tower *C B* (Fig. 107), we first measure the distance from the bottom of the tower, *B*, to a station at the point *A*, which suppose to be one hundred feet. From this station, by a quadrant or other angular instrument, we take the angle of elevation of the top of the tower, or the angle *C A B*, which suppose to be forty-seven and a half degrees. Here we have a triangle in which we have one side, *A B*, and two angles; namely, the angle at A=47½°, and the angle at *B*, which is a right angle, or 90°, as the tower is supposed to stand perpendicular to the ground; therefore, the side *C B*, which is the hight of the tower, can be found, and likewise the other side, *A C*, if required. To find *C B*, the hight of the tower, we make *A B* the radius of the circle, a portion of which measures the angle *A;* and the side *B C*, or the hight of the tower, becomes the tangent of that angle. And as there is a certain known proportion between the radius of every circle and the tangent, the hight of the tower will be found by the following proportion: As the radius: is to the tangent of the angle *A*, 47½° :: so is the side *A B*, 100 feet: to *C B*, the hight of the tower=109⅛ feet. The following is the calculation by logarithms:

Logarithm of the 2d term— Tangent of 47½°	10.0379475
Logarithm of *A B*=100 feet— 3d term	2.0000000
	12.0379475
Logarithm of radius—1st term	10.0000000
Logarithm of *C B*, 4th term= 109⅛ feet	2.0379475

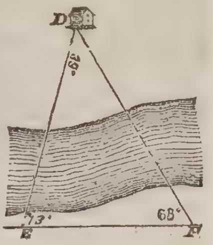
By this calculation the hight of the tower is found with the greatest nicety, provided the measurement of the side *A B*, and the angle *A*, have been taken with accuracy.

Again: Suppose it were required to measure the distance between a tree *E*, and a house *D*, on the opposite side of a river. We first measure a space from *E* to *F* (Fig. 108), suppose 200 yards, in a right line, and then find the angles *E* and *F* at each end of this line. Suppose the angle at *E* to be seventy-three degrees and the angle at *F* sixty-eight degrees. As all the angles of a triangle are equal to two right angles, or 180°, if we add these two angles and subtract their sum from 180°, the remainder, 39°, will be the measure of the angle at *D*. It is a demonstrated proposition in trigonometry, that *in any plane triangle, the sides are in the same proportion as the sines of the opposite angles.* A sine is a line drawn through one extremity of an arc perpendicular upon the diameter or radius passing through the other extremity, as *a d* (Fig. 107). In order, then, to find the distance (*E D*) between the tree and the house on the other side of the river, we state the following proportion: As the sine of *D*, 38°, the angle opposite to *E F*, the known side: is to the sine of the angle *F*, 68°, opposite the side sought, *E D* : : so is the length of the line *E F*=200 yards: to the distance, *E D*, between the tre and the house=294⅔ yards. The following is the operation by logarithms:

107.



108.

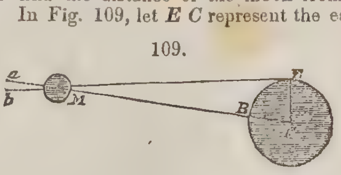


2d term—Sine of angle, *F*=68°	9.9671659
3d term—*E F*=200 yards. Log.	2.3010300
	12.2681959
1st term—Sine of angle, *D*=39°	9.7988718
4th term—*D E*=294⅔ yards=	2.4693241

In these examples the logarithms of the second and third terms of the proportion are added, and from their sum the logarithm of the first term is subtracted, which leaves the logarithm of the fourth term; as in common numbers, the second and third terms are multiplied together, and their product divided by the first term; addition of logarithms corresponding to multiplication of whole numbers, and subtraction to division. The logarithms of common numbers, and of sines and tangents, are found in tables prepared for the purposes of calculation.

I shall now state an example or two in reference to the celestial bodies. Suppose it is required to find the distance of the moon from the earth. In Fig. 109, let *E C* represent the earth;

109.



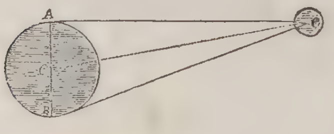
M, the moon; *E*, the the place of a spectator observing the moon in his sensible horizon; *E M b* and *C M a* the direction of the moon as seen from the center of the earth at *C*, or from its surface at *B*; *a* the place of the moon as seen from the center, and *b* its place as seen from the surface at *E*; or, in other words, the moon's *horizontal parallax*. This parallax, at the moon's mean distance from the earth, is found to be 57 minutes, 5 seconds. Here, then, we have a triangle, *C E M*, of which we have one side and two angles given. The side given is the semidiameter of the earth, *E C*, which is equal to 3965 miles; the angle at *E* is a right angle, or ninety degrees, for it forms a tangent to the circle at *E*; the angle at *M* is the horizontal parallax, which is found by observation. From these data, the side *M C*, or the distance of the moon from the center of the earth, may be easily found. If we make *C M* radius, *E C* will be the sine of the angle *M*; and the distance of the moon is found from the following proportion : As *E C*, the sine of fifty-seven minutes, five seconds : is to 3965, the number of miles in the semidiameter of the earth : : so is *M C*, the radius : to a fourth number, 238,800=*M C*=the distance of the moon from the center of the earth.

2d term—3965=the earth's semidiameter	3.598243
3d term—Radius	10.000000
	13.598243
1st term—Sine of 57 minutes, 5 seconds	8.220215
M C, distance of the moon, 238,800 miles=	5.378028

According to this calculation, the moon is two hundred and thirty-eight thousand, eight hundred miles from the earth. In round numbers we generally say that the moon is 240,000 miles distant; and, in point of fact, she is sometimes considerably more than 240,000 miles distant, and sometimes less than the number above stated, as she moves in an elliptical orbit, her horizontal parallax varying from 54 to above 60 minutes.

To find the Diameter of the Moon.—In Fig. 110 let *A G B* represent the moon, and *C* an observer at the earth. The apparent diameter of the moon at its mean distance, as measured by a micrometer, is 31 minutes, 26 seconds, represented by the angle *A C B*; the half of this, or the angle formed by the semidiameter of the moon, *A C G*, is 15 minutes, 43 seconds. The distance of the moon, *G C*, is supposed to be found as above stated, namely, 238,800 miles. Here, then, we have the angle *C A G*, which is a right angle, and the angle *A C G*=15′ 43″, which is found by observation; and the side *C G*, or the distance of the moon from the earth. We can therefore find the side *A G*, or the semidiameter of the moon, by the following proportion : As radius : is to *C G*, the distance of the moon, 238,800 miles : : so is the sine of *A C G*, 15′ 43″ : to the number of miles contained in the moon's semidiameter, *A G*=1091½, which, being doubled, gives 2183 miles as the diameter of the moon.

110.



2d term—*C G*=238,800—Log.		5.378028
3d term—Sine of *A C G*, 15′ 43″		7.660059
		13.038087
1st term—Radius		10.000000
Semidiameter of the moon,	1,091½=	3.03808″
	2	
Diameter of the moon=	2,183	

Such is the general mode by which the distances and magnitudes of the heavenly bodies are calculated. I am aware that the general reader who is unacquainted with the principles of trigonometry, may find a little difficulty in comprehending the statements and calculations given above; but my design simply was to convey an idea of the *principle* on which astronomers proceed in their computations of the distances and bulks of the celestial orbs, and to excite those who are anxious to understand the subject, to engage in the study of plane trigonometry, a study which presents no great difficulty to any one who is already a proficient in common arithmetic. I conclude the subject with the following

General Remarks.—1. Before the bulks of the heavenly bodies can be determined, their *distances* from the earth must first be ascertained. When their distances are found, it is quite an easy matter to determine their *real* bulks from their *apparent* magnitudes. 2. *The semidiameter of the earth forms the groundwork of all our calculations respecting the distances of the celestial orbs.* Were we ignorant of the dimensions of the earth, we could not find the real distance and magnitude of any heavenly body; and it is owing to the comparatively small diameter of the earth that it becomes difficult in some cases to determine with accuracy the parallaxes of certain heavenly bodies. Were we placed on a planet such as Jupiter, whose diameter is more than eleven times that of our globe, it would be much more easy to find the parallaxes of the sun and planets. The parallaxes of Jupiter's moons, as observed from that planet, will form pretty large angles and be easily perceptible; and so likewise will be the parallaxes of the sun and the other planets which are visible from that globe. 3. *The chief difficulty* in finding the distances of the heavenly bodies *is to determine accurately the precise quantity of their parallaxes.* In the case of the moon there is no difficulty, as her horizontal parallax amounts to nearly one degree, and can be taken with the greatest nicety; but the sun's parallax is so small that it was some time before it was accurately determined. It was for this purpose, among others, that Captain Cook's first expedition to the Pacific Ocean was undertaken, in order that the astronomers connected with it might observe the transit of Venus at the Island of Tahiti; since which time the sun's distance has been ascertained within the one eighty-seventh part of his true distance, which likewise determines very nearly the true proportional distance and magnitudes of all the planets. This circumstance accounts for the fact, that in books of astronomy published about a century ago, the distances and magnitudes of the sun and planets are estimated somewhat lower than they are now found to be, the improvements which have been made in the construction of astronomical instruments having enabled modern observers to measure parallactic angles with greater niceness and accuracy. 4. When the parallax of any heavenly body is once accurately found, and its apparent diameter measured, its real distance and bulk can be as certainly known as the price of any quantity of merchandise which is calculated by the rule of proportion. 5. From what has been stated above, we may learn the importance of knowing all the properties of a triangle, and the art of measuring angles. At first sight it may appear to be a matter of trivial importance to know that the radius of a circle bears a certain known proportion to the sine or tangent of a certain angle; that the *sides* of any triangle are in the same proportion as the *sines* of the opposite angles; and that the three angles of every plane triangle are exactly equal to two right angles.—Yet such truths form the foundation of all the discoveries which have been made respecting the magnitudes and distances of the great bodies of the universe, and of the ample conceptions we are now enabled to form of the vast extent of creation, and of the attributes of its adorable Creator.

Those persons who feel themselves unable to comprehend clearly the principles and calculations above stated, may rest satisfied with the general deductions of astronomers respecting the distances and magnitudes of the sun and planets, from the following considerations: 1. *The general agreement of all modern astronomers as to these deductions.* However much astronomers may differ in regard to certain subordinate opinions or conjectures respecting certain phenomena, they all agree with respect to the bulks and distances of the planetary orbs, and the mode by which they are ascertained. If there were any fallacy in their calculations, such is the tendency of human nature to find fault, it would soon be pointed out.—2. The consideration of *the accuracy with which astronomers predict certain celestial phenomena* should induce persons unskilled in this science to rely on the conclusions deduced by astronomers. They are fully aware that the eclipses of the sun and moon are calculated and predicted with the utmost accuracy. The very moment of their beginning, middle, and end, and the places where they will be visible, are foretold to a nicety; the nature and magnitude of the eclipse, and all the circumstances connected with it, determined; and that, too, for more than a century to come. All the eclipses which have happened of late years were calculated more than half a century ago, and are to be found recorded in the writings of astronomers. They can likewise tell when Mars, Jupiter, or Saturn is to suffer an occultation by the moon, the time when it will begin and end, the particular part of the moon's limb behind which the planet will disappear, the point on the opposite limb where it will again emerge, and the places of the earth where the occultation will be visible. They can likewise predict the precise moment when any of the fixed stars—even those invisible to the naked eye—shall suffer an occultation by the moon or by any of the planets; and such occultations of the stars and planets are stated in the "Nautical Almanac," and similar publications, three or four years before they actually happen.

The precise time, likewise, when the planets Mercury and Venus will appear to pass across the sun's disc, has been predicted for a century before such events happened, and such transits have been calculated for several centuries to come, and will most assuredly take place, as they have hitherto done, if the laws of nature continue to operate as in ages past. Dr. Halley, in 1691, predicted the transit of Venus that happened in 1761, seventy years before it took place; and not only so, but he calculated the precise hour in which the planet would appear to touch the limb of the sun as seen from different places; the particular part of the sun's margin where the planet would appear and disappear, and the precise course it would take in passing across the disc of the sun; the appearance it would present in different regions of the globe, and the most proper places in both hemispheres were pointed out where either its beginning, middle, or end would be most distinctly observed, in order to accomplish the object in view; namely, the determination of the exact distance of the sun. All which calculations and predictions were ultimately found to be correct; and astronomers were sent to different parts of the globe to observe this interesting phenomenon, which happens only once or twice in the course of a century. The same astronomer calculated the period of a comet, distinguished by the name of "Halley's Comet," and predicted the periods when it would return It was seen in England in 1682, and Dr. Halley calculated that it would again appear in this part of the system in 1758; and it accordingly made its appearance in December, 1758, and arrived at its perihelion on the 13th of March, 1759. The validity of these calculations and predictions has been again verified by the reappearance of the same comet in 1835, just at the time when it was expected, which proves that it completes its course in the period which had been predicted, namely, seventy-six years, and will, doubtless, again revisit this part of the system in the year 1911 or 1912. Astronomers can likewise point out, even in the day-time, the different stars and planets which are above the horizon, though invisible to the unassisted eye. I have sometimes surprised even gentlemen of intelligence by showing them, through an equatorial telescope, the star *Arcturus*, and, in a minute or two afterward, the star *Altair* in another part of the heavens, and the planet Venus in another quarter in the form of a brilliant crescent, while the sun was several hours above the horizon, and shining in its greatest brightness, and while these bodies are every moment shifting their apparent positions; all which is quite easy to be accomplished by every one who understands the motions of the heavenly bodies and the first principles of astronomy.

Now as the above facts are indisputable, and every one who feels an interest in the subject may satisfy himself as to their reality, it is evident to a demonstration that the principles of science on which such calculations and predictions proceed are not mere conjectures or precarious suppositions, but have a real foundation in the constitution of nature and in the fundamental laws which govern the universe. And as the knowledge of astronomers cannot be questioned in relation to the phenomena to which I refer, it would be unreasonable, and injurious to the moral characters of such men, to call in question their modes of ascertaining the distances of the sun and the planetary bodies, and the deductions they have made in relation to their astonishing magnitudes. There is no science whose principles are more certain and demonstrable than those of astronomy. No labor or expense has been spared to extend its observations, and to render them accurate in the extreme; and the noblest efforts of genius have been called forth to establish its truths on a basis immutable as the laws of the universe; and, therefore, the man who questions the leading facts and deductions of this science only proclaims his own imbecility and ignorance.

CHAPTER VIII.

ON THE SCENERY OF THE HEAVENS, AS VIEWED FROM THE SURFACES OF THE DIFFERENT PLANETS AND THEIR SATELLITES.

This is a department of descriptive astronomy which is seldom noticed in books professedly written to illustrate the objects of this science. It is here introduced not only as an interesting subject of contemplation, but as an illustration of the *variety* which the Creator has introduced into the scenes of the universe, and as a collateral or presumptive argument in support of the doctrine of a plurality of worlds.

Before proceeding to the particular descriptions I intend to give, it may be proper to state the following *General Remarks:* 1. The different clusters of stars or the *constellations* will appear exactly the same when viewed from the other planets as to the inhabitants of our globe. For example, the constellations of *Orion* and of the *Great Bear* will appear of the same shape or figure, and all the stars of which they are composed will appear to have the same arrangement and the same relative distances from each other and from neighboring stars, as they do to us. 2. The *apparent magnitudes* of the fixed stars will appear exactly the same as they do when viewed from our world; that is, they will appear no larger than shining points of different magnitudes, even when viewed from the most distant planets. The reason of this and of the preceding position is obvious from the consideration of the *immense distance* of those bodies; for although we are 190 millions of miles nearer some of the fixed stars at one time of the year than at another, yet there appears no sensible difference in their size or arrangement, and although we were placed on the remotest planet of the system, we have no reason to believe that any material difference in this respect would be perceived; for the distances of the remoter planets bear no sensible proportion to the distances of the fixed stars. Even the distance of the planet Uranus, great as it is, which would require four hundred years for a cannon ball to move over the space which intervenes between that orb and us, is less than the ten-thousandth part of the distance of the nearest star; and, therefore, can produce no sensible difference in the general aspect of the starry firmament. 3. Though the general arrangement of the stars and constellations will appear the same as to us, yet the different directions of the axes of some of the planets from that of the earth *will cause a different appearance in their apparent diurnal revolutions.* Some stars which appear in our equator may, in other planets, appear near one of their poles, and our pole star may appear near their equator.

In the following descriptions it is taken for granted that the general laws of vision are materially the same in all the planetary bodies as in that part of the system which we occupy. Of this we have no reason to doubt, as the same identical light which illuminates the earth likewise enlightens all the planets and their satellites. It originates from the same source, it is refracted and reflected by the same laws, and must produc colors similar or analogous to those which diversify the surface of our globe; though, perhaps susceptible of numerous modifications in other regions, according to the nature of the atmospheres through which it passes, and the quality of the objects on which it falls. The descriptions that follow likewise proceed on the supposition that the *extent of vision* is the same as ours. This in all probability, is not the case. It is more probable that, in certain worlds, the organs of vision of their inhabitants may be far more exquisite than ours, and capable of surveying with distinctness a much more extensive range of view. But as we are ignorant of such particulars, we can only proceed on the assumption of what would appear to eyes constituted like ours were we placed on the surfaces of the different planets.

Scenery of the Heavens from the Planet Mercury.—This planet being so near the sun ha prevented us from discovering various particulars which have been ascertained in relation to severa of the other planets; and, therefore, little can be said respecting its celestial scenery. The starry heavens will appear to move around it every twenty-four hours, as they do to us, if the observations of M. Schroeter, formerly stated (p. 27) be correct; but the direction of its axis of rotation is not known, and, therefore, we cannot tell what stars will appear near its equator or its poles. The sun will present a surface in the heavens seven times as large as he does to us, and, of course, will exhibit a very august and brilliant appearance in the sky, and will produce a corresponding brightness and vividness of color on the objects which are distributed over the surface of the planet. Both Venus and the earth will appear as *superior* planets; and when Venus is near its opposition to the sun, at which time it will rise when the sun sets, it will present a very brillian appearance to the inhabitants of Mercury, and serve the purposes of a small moon, to illuminate the evenings in the absence of the sun. As Venus presents a full enlightened hemisphere at this period to the inhabitants of Mercury, it will exhibit a surface six or seven times larger than it does to us when it shines with its greatest brilliancy, and, therefore, will appear a very bright and conspicuous object in the firmament of this planet. At all other times it will appear at least two or three times larger than it ever does as seen from the earth. It will generally appear round, but at certain times it will exhibit a gibbous phase, as the planet Mars frequently does to us. It will never appear to the inhabitants of Mercury in the form of a crescent or half moon, as it sometimes does through our telescopes. There is no celestial body within the range of this planet with which we are acquainted which will exhibit either a half moon or a crescent phase unless it be accompanied with a satellite. The earth is another object in the firmament of Mercury which will appear next in splendor to Venus. The earth and Venus are nearly of an equal size, Venus being only 130 miles less in diameter than the earth; but the earth being nearly double the distance of Venus from Mercury, its apparent size, at the time of its opposition to the sun, will be only about half that of Venus. The earth, however, at this period, will appear in the sky of Mercury of a size and splendor three or four times greater than Venus does to us at the period of its greatest brilliancy. Our moon will also be seen like a star accompanying the earth, sometimes approaching to or receding farther from the earth, and sometimes hidden from the view by passing across the disc of the earth or through its shadow. It will probably appear about the size and brightness of Mars or Saturn, as seen in our sky. The earth with its satellite, and Venus, will be seen near the same point of the heavens at the end of every nineteen months, when they will for some time appear the most conspicuous objects in the heavens, and will diffuse a considerable portion of light in the absence of the sun. At other periods, the one will rise in the eastern horizon as the other sets in the western; so that the inhabitants of Mercury will seldom be without a conspicuous object in their heavens, diffusing a luster far superior to that of any other stars or planets. The earth will be in opposition to the sun every four months, and Venus after a period of five months. The planets Mars, Jupiter, and Saturn will appear nearly as they do to us, but with a somewhat inferior degree of magnitude and brilliancy, particularly in the case of Mars. The period of the annual revolution of Mercury being eighty-eight days, the sun will appear to move from west to east through the circle of the heavens at a rate more than four times greater than his apparent motion through the signs of our zodiac.

Appearance of the Heavens as viewed from Venus.—To the inhabitants of this planet the heavens will present an aspect nearly similar to that of Mercury, with a few variations. Mercury will be to Venus an *inferior* planet, which will never appear beyond thirty-eight or forty degrees of the sun. It will appear in the evening after sunset for the space of two or three hours when near its elongation, and in the morning before sunrise when in the opposite part of its course, and will alternately be a morning and an evening star to Venus, as that planet is to us, but with a less degree of splendor. The most splendid object in the nocturnal sky of Venus will be the *earth*, when in opposition to the sun, when it will appear with a magnitude and splendor five or six times greater than either Jupiter or Venus appear to us at the time of their greatest brilliancy. It will serve, in a great measure, the purpose of a moon to Venus, if this planet have no satellite, and will cause the several objects on its surface to project distinct and well-defined shadows, as our moon does when she appears a crescent. Our moon, in its revolutions round the earth, will likewise appear a prominent object in the heavens, and will probably appear about the size that Jupiter appears to us. Her occultations, eclipses, and transits across the earth's disc will be distinctly visible. With telescopes such as the best of ours the earth would appear from Venus a much larger and more variegated object than any of the planets do to us when viewed with high magnifying powers. The forms of our different continents, seas, and islands, the different strata of clouds in our atmosphere, with their several changes and motions, and the earth's diurnal rotation, would, in all probability, be distinctly perceived. Even the varieties which distinguish the surface of our moon would be visible with telescopes of high magnifying power. The circumstances now stated prove the connection of the different parts of the planetary system with one another, and that the Creator has so arranged this system as to render one world, in a certain degree, subservient to the benefit of another. The earth serves as a large and splendid moon to the lunar inhabitants; it serves, in a certain degree, the purpose of a small moon to Mercury; it serves the purpose of a larger moon, by exhibiting a surface and a radiance four times greater to the inhabitants of Venus; and it serves as a morning and an evening star to the planet Mars. So that, while we feel enjoyment in contemplating the moon walking in brightness, and hail with pleasure the morning star as the harbinger of day, and feel a delight in surveying those nocturnal orbs through our telescopes, the globe on which we dwell affords similar enjoyments to the intellectual beings in neighboring worlds, who behold our habitation from afar as a bright speck upon their firmament, diffusing amid the shades of night a mild degree of radiance. From Venus the planets Saturn and Jupiter will appear nearly as they do to us, but the planet Mars will appear considerably smaller. The sun in this planet will present a surface twice as large as he does in our sky, and will appear to make a revolution round the heavens in the course of seven months and a half, which completes the year of Venus.

The Heavens as viewed from Mars.—From this planet the earth will at certain periods be distinctly seen, but it will present a different aspect both in its general appearance and its apparent motions from what it does to the inhabitants of Venus. To Mars the earth is an inferior planet, whose orbit is *within* the orbit of Mars. It will therefore, be seen only as a morning and an evening star, as Venus appears to us; but with a less degree of magnitude and brightness, since Mars is at a greater distance from the earth than the earth is from Venus. It will present to Mars successively the form of a *crescent*, a *half-moon*, and a *gibbous* phase, but will seldom or never be seen as a full enlightened hemisphere, on account of its proximity to the sun, when its enlightened surface is fully turned toward the planet; nor will it ever appear farther removed from the sun, either in the mornings or evenings, than forty-eight degrees, so that the earth will never appear in the firmament of Mars about midnight. The earth will likewise be sometimes seen to pass across the sun's disc like a round black spot, as Venus and Mercury at certain periods appear to us; but the planet Mercury will never be seen from Mars on account of its smallness and its nearness to the sun; for at its greatest elongation it will be only a few degrees from the sun's margin, and will consequently be immersed in his rays. The only time in which it might happen to be detected will be when it makes a transit across the solar disc. Venus will be as seldom seen by the inhabitants of Mars as Mercury is to us. Our moon will likewise be seen from Mars like a small star accompanying the earth, sometimes appearing to the east and sometimes to the west of the earth, but never at a greater distance from each other than fifteen minutes of a degree, or about half the apparent breadth of the moon; and with telescopes such as ours all its phases and eclipses might be distinctly perceived. The planets Jupiter and Saturn will appear to Mars nearly as they do to us. At the time of Jupiter's opposition to the sun that planet will appear a *slight degree* larger, as Mars is then fifty millions of miles nearer it than we are; but Saturn will not appear sensibly larger than to us; and it is likely that the planets Uranus, Vesta, Juno, Ceres and Pallas will not be more distinguishable than they are from our globe. The point *Aries*, on the ecliptic of Mars, or one of the points where its ecliptic and equator intersect each other, corresponds to 19° 28′ of our sign *Sagittarius*. In consequence of this, the poles of Mars will be directed to points of the heavens considerably different from our polar points, and its equator will pass through a different series of stars from that which marks our equator, which will cause the different stars and constellations in their apparent diurnal revolution to present a different aspect from what they do in their apparent movements round our globe.

The Heavens, as viewed from Vesta, Juno, Ceres and Pallas.—These planets, being so very nearly at the same mean distance from the sun, the appearance of the heavens will be nearly the same to the inhabitants [if any] of each of these bodies. The planet Jupiter will be the most conspicuous object in the nocturnal sky of all these planets, and will appear with nearly three times the size and splendor that he does when seen from the earth, so as to exhibit the appearance of a small brilliant moon. Saturn will appear somewhat larger and brighter than to us, but the difference in his appearance will be inconsiderable; nor will Uranus be more distinctly visible than from the earth. At other times, when near their conjunction with the sun, these planets will appear smaller than to us. Mars will sometimes appear as a morning and an evening star, but he will always be in the immediate neighborhood of the sun, and will present a surface much less in apparent size than he does to the earth. The earth will seldom be seen on account of its proximity to the sun; and Venus and Mercury will be altogether invisible, unless when they transit the solar disc. It is likely that, at certain times, the planets Vesta, Juno, Ceres, and Pallas will exhibit an uncommon, and occasionally a brilliant appearance in the firmament of each other. As their distances from the sun are so nearly the same, they may occasionally approach each other so as to be ten times nearer to one another in one part of their course than at another. It is even possible that they might approach within a few miles of each other, or even come into collision. These different positions in which they may be placed in relation to one another will doubtless produce a great variety in the appearances they present in their respective firmaments; so that at one time they may present in the visible firmament a surface a hundred or even two hundred times greater than they do in other parts of their annual revolutions. It is probable, therefore, that the diversified aspects of these planets, in respect to each other, will form the most striking phenomena which diversify their nocturnal heavens. In conseqence of the great eccentricity of the orbit of Pallas, the sun will appear much larger to this planet in one part of its revolution than it does at another.

Celestial Scenery from Jupiter.—The only planet whose appearance will be conspicuous in the firmament of Jupiter is the planet *Saturn*, which will appear with a surface four times greater than is exhibited in our sky, and will appear larger than either Jupiter or Venus does to us, particularly at the time of its opposition to the sun At certain other periods, when near the time of its conjunction with the sun, it will appear considerably smaller than when viewed from the earth; as, at such periods, Saturn is nearly fourteen hundred millions of miles distant from Jupiter, while it is never beyond ten hundred millions from the earth, even at its remotest distance. The planet Uranus, which is scarcely visible to our unassisted sight, will not be much more distinguishable at Jupiter than with us, even at the period of its opposition, although Jupiter is at that time 400,000,000 of miles nearer it than a spectator on the earth. At other times, when near its conjunction with the sun, it will be 2,300,000,000 of miles from Jupiter, which is 400,000,000 of miles more distant than it ever is from us. Mars will scarcely be seen from Jupiter, both on account of his smallness and his proximity to the sun; for at his greatest elevation he can never be more than eighteen degrees from that luminary. The earth, too, will be invisible from Jupiter, both on account of its small size, its distance, and its being in the immediate vicinity of the sun, and immersed in its rays; so that the inhabitants of this planet will scarcely suspect that such a globe as that on which we dwell exists in the universe. It is a humiliating consideration to reflect, that before we have passed over one fourth part of the extent of our system, this earth, with all its kingdoms and fancied grandeur, of which mortals are so proud, vanishes from the sight, as if it were a mere atom in creation, and is altogether unnoticed and unknown. It is calculated to convey a lesson of *humility* and of humanity to those proud and ambitious mortals who glory in their riches, and in the small patches of earthly territory they have acquired at the expense of the blood of thousands of their fellow-men, and who fancy themselves to be a species of demi-gods, because they have assisted in the conquest of nations, and in spreading ruin and devastation over the earth. Let us wing our flight to Jupiter or Saturn, which appear so conspicuous in our nocturnal sky, and before we have arrived at the middle point of the planetary system this globe on which we tread, with all the proud mortals that dwell upon its surface, vanishes from the sight as a particle of water, with its microscopic animalculæ, dropped into the ocean, disappears for ever. In those regions more expansive and magnificent scenes open to view, and their inhabitants, if ever they have heard of such beings as fallen man, look down with an eye of pity and commiseration, and view their characters and conduct with a holy indignation and contempt.

Venus and Mercury will, of course, be altogether invisible from the surface of Jupiter, and it is questionable whether even the planets Vesta, Juno, Ceres, and Pallas will be perceived. But although so few of the primary planets are seen in the nocturnal sky of this planet, its firmament will present a most splendid and variegated aspect by the diversified phases, eclipses, and movements of the satellites with which it is encircled; so that its inhabitants will be more charmed and interested by the phenomena presented by their own moons than by their contemplation of the other bodies of the system. But as I have already described the appearances of the moons, as seen from Jupiter (p. 95, chap. iv, sec. ii.) it is unnecessary to enlarge.

Scenery of the Heavens as viewed from Saturn.—The firmament of Saturn will unquestionably present to view a more magnificent and diversified scene of celestial phenomena than that of any other planet of our system. It is placed nearly in the middle of that space which intervenes between the sun and the orbit of the remotest planet. Including its rings and satellites, it may be considered as the largest body or system of bodies within the limits of the solar system; and it excels them all in the sublime and diversified apparatus with which it is accompanied. In these respects Saturn may justly be considered as the sovereign among the planetary hosts. The prominent parts of its celestial scenery may be considered as belonging to its own system of rings and satellites, and the views which will occasionally be opened of the firmament of the fixed stars; for few of the other planets will make their appearance in its sky. Jupiter will appear alternately as a morning and an evening star, with about the same degree of brilliancy it exhibits to us; but it will seldom be conspicuous except near the period of its greatest elongation, and it will never appear to remove from the sun farther than thirty-seven degrees, and, consequently, will not appear so conspicuous nor for such a length of time, as Venus does to us. Uranus is the only other planet which will be seen from Saturn, and it will there be distinctly perceptible, like a star of the third magnitude, when near the time of its opposition to the sun. But near the time of its conjunction it will be completely invisible, being then eighteen hundred millions of miles more distant than at the opposition, and eight hundred millions of miles more distant from Saturn than it ever is from the earth at any period. All the other eight planets, together with our moon, will be far beyond the reach of a spectator in Saturn, unless he be furnished with organs of vision far superior to ours in their "space-penetrating power." It is not improbable that more *comets* will be seen in their course from the sun, from the distant regions in which Saturn moves, than from that part of the system in which we are placed. Some of these bodies, when they pass beyond the limits of our view, will be visible beyond the orbit of Saturn; and as their motions in those distant spaces are much slower than when near the sun, they will remain visible for a longer time, when they happen to make their appearance, than they do when passing through our part of the system.

Having already given a pretty full description of the appearance of the rings of this planet as viewed from its surface (p. 69–71), and of the phenomena exhibited by its satellites (p. 98), it is unnecessary to introduce the subject in this place. I shall only remark further, in regard to the rings which encompass this planet, that, beside the light they reflect on the planet, and the brilliant aspect they present in its firmament, they cast a great diversity of shadows upon the surface of the planet, of different breadths at different times and places, and it will require a considerable degree of attention and investigation on the part of its inhabitants to determine whence the shadows proceed. For when the dark sides of the rings are turned toward them, they will, in all probability, be invisible in their sky, as the dark side of the moon or of Venus is to us, and, therefore, they may be at a loss, in some instances, to discover the causes of such varieties of light and shade. For, although *we* are placed in a convenient position to perceive that they are in reality *complete rings* which environ the body of Saturn, yet it will not be so easy for *its inhabitants* to discover this fact; as only a portion of the rings will be visible in some places, and in the regions near the poles they will appear only like a bright streak in the horizon. They will naturally conclude that the shadows proceed from some body in their firmament; but they will require to make a great variety of observations, to compare them together, and to investigate the doctrine of parallaxes, before they come to the conclusion that the phenomena alluded to are caused by mighty rings which encompass their habitation.

As the diameter of Saturn is ten times the diameter of the earth, it will be comparatively easy for its inhabitants to find the parallaxes, distances, and magnitudes of its different satellites, and likewise of Jupiter and Uranus, which are the only planets visible from Saturn. To those who dwell in its equatorial regions, the motion of the rings around their axis will furnish an accurate measure of time, as well as the diurnal rotation of the planet; and to all places on its surface the periodical revolutions of its different satellites will afford various measures, divisions, and subdivisions of the lapse of duration. The sun will appear from this planet of a size about five times the diameter which Jupiter presents to our view, or about 1-9th or 1-10th part of the diameter of the sun as seen from the earth; but, notwithstanding, there appears no deficiency of light on the surface of Saturn.

Let us, then, suppose two mighty arches in Saturn's nocturnal sky, appearing to the inhabitants of one region like broad semicircles of light extending completely across the heavens, to other regions like large segments of an arch, the highest point of which elevated only twenty or thirty degrees above the horizon, and to the places adjacent to the polar regions as a zone of light hovering in the horizon; let us suppose the distant stars twinkling through the dark space which separates the rings; the sun eclipsed at noon, in one place, by the upper edge of the rings, and in another place by the lower; the brightness of this luminary waxing dimmer and dimmer, and in a few hours hidden by an invisible object, not to appear again until after a lapse of fourteen years; and the inhabitants of this region of shadows occasionally traveling to those countries where the rings are enlightened and the sun is constantly shining: let us suppose one moon, nine times as large in apparent size as ours, suspended in the canopy of heaven: another, three times as large as ours, in another quarter of the sky; a third twice as large; a fourth about the apparent size of our moon; and a fifth, sixth, and seventh of different apparent magnitudes; some of them appearing with a crescent, some with a gibbous phase, and others with a full enlightened hemisphere; some rising, some setting; one entering into an eclipse, and another emerging from it; let us suppose such scenes as these, and we may acquire a general idea of the phenomena presented in the heavens of Saturn.

Scenery of the Heavens in Uranus.—The orbit of this planet, so far as we know, forms the extreme boundary of the planetary system. Being so far removed from the center of the system, almost all the other planets and their satellites will be invisible to a spectator placed on this orb. The only planet which will be distinctly visible is Saturn, which will be seen occasionally as a morning and an evening star, and will appear nearly of the same size as to us; but as it will always be seen in the immediate neighborhood of the sun, it will only be visible at certain distant periods, or intervals of fifteen years, and will appear about as near to the sun as Mercury does when viewed from the earth. Its rings and satellites might occasionally be perceived with such instruments as our best telescopes when it is near the points of its greatest elongation. It is not probable that Jupiter will be visible from this planet on account of its proximity to the sun. If ever it be visible, it will only be for a short time, after periods of six or eight years have elapsed. From Uranus it is likely that the motions of some of the comets will be seen to advantage, and for a considerable length of time, as the motions of these bodies must be comparatively slow in those distant regions.—It is not improbable that, in their course from the sun, the motions of some of these bodies may be followed to the extreme point of their trajectories, and their courses traced in their return toward the central luminary; and that they may be visible in the firmament of this planet for months, and even for years together. It is likewise probable that, from Uranus, the parallax of the nearest fixed stars, and, consequently, their *distance*, may be ascertained. For the diameter of its orbit, which is 3,600,000,000 of miles, will form a pretty extensive *base line* for this purpose, and will produce a parallax nineteen times greater than that of the diameter of the earth's annual orbit, which is only 190 millions of miles. But the determination of such a parallax would require a series of observations made at intervals of forty-two years, namely, at two opposite points of the orbit of Uranus, in moving between which it occupies a space of nearly forty-two years.

The most splendid and interesting scenery in the firmament of this planet will be produced by the phases, eclipses, revolutions, and various aspects of its moons. Six of these bodies have been discovered revolving around it, and it is not improbable that several more (perhaps three or four) may be connected with this distant orb, the smallness of which, and their nearness to the planet, may forever prevent them from being detected by our most powerful instruments. Let us suppose, then, one satellite presenting a surface in the sky eight or ten times larger than our moon; a second five or six times larger; a third three times larger; a fourth twice as large; a fifth about the same size as the moon; a sixth somewhat smaller; and, perhaps, three or four others of different apparent dimensions: let us suppose two or three of these, of different phases, moving along the concave of the sky, at one period four or five of them dispersed through the heavens; one rising above the horizon, one setting, one on the meridian, one toward the north, and another toward the south; at another period five or six of them displaying their luster in the form of a half moon or a crescent in one quarter of the heavens, and at another time the whole of these moons shining, with full enlightened hemispheres, in one glorious assemblage, and we shall have a faint idea of the beauty, variety, and sublimity of the firmament of Uranus. What is deficient in respect of the invisibility of the other planets is amply compensated by its assemblage of satellites, which illuminate and diversify its nocturnal sky. Although this planet is more than seventeen hundred millions of miles nearer some of the fixed stars than we are, yet those luminaries will not appear sensibly larger, as seen from Uranus, than they do from our globe. For even this immense interval would not subtend an angle of nineteen seconds, or the 1-190th part of a degree, as seen from the nearest star; and, of course, all the constellations will present the same figures and relative aspects as they do to us, with this difference only, that those stars which are near our equator or tropics may be near the poles or polar circles of Uranus. This depends entirely upon the position of its axis of rotation, which is to us unknown. The sun will appear so small from this planet, that its apparent diameter will not exceed 2½ times the apparent diameter of Jupiter; but its light is not so weak as we might be apt to imagine from this circumstance, as is evident from the brightness it exhibits when viewed with a telescope in the night-time, and likewise from the well-known phenomenon that when the sun is eclipsed to us, so as to have only the *one-fortieth* part of its disc left uncovered by the moon, the diminution of light is not very sensible; and it has been frequently noticed that, at the end of the darkness in total eclipses, when the sun's western limb begins to be visible, and seems no bigger than a thread of fine silver wire, the increase of light is so considerable, and so quickly illuminates all surrounding objects, as to strike the spectators with surprise. But whatever deficiency of light there may be on this planet, we may rest assured, from a consideration of the *wisdom* and benevolence of the Creator, that this deficiency is amply compensated, either by the objects on which it falls being endowed with a strong reflective power, or by the organs of vision being adapted to the light received, or by some other contrivances with which we are unacquainted

SCENERY OF THE HEAVENS AS SEEN FROM THE SATELLITES.

Celestial Scenery of the Moon.—Although the moon is the nearest body to the earth, and its constant attendant, yet its celestial phenomena will, in a variety of respects, be very different from ours. The earth will appear to be the most splendid orb in its nocturnal sky, and its various phases and relative positions will form a subject of interesting inquiry and contemplation to its inhabitants. It will present the appearance of a globe in the sky *thirteen times larger* than the moon does to us, and will diffuse nearly a corresponding portion of light on the mountains and vales on the lunar surface. As the moon always presents nearly the same side to our view, so the earth will be visible to only one half of the lunar inhabitants. Those who live on the opposite side of the moon, which is never turned toward our globe, will never see the earth in the sky unless they undertake a journey to the opposite hemisphere for this purpose; and those who dwell near the central parts of that hemisphere which is turned from our globe will require to travel more than 1500 miles before they can behold the large globe of the earth suspended in the sky. To all those to whom the earth is visible, it will appear *fixed* and immovable in the same relative point of the sky, or, at least, will appear to have no circular motion round the heavens. To a spectator placed in the middle of the moon's visible hemisphere, the earth will appear directly in the zenith or over head, and will always seem to be fixed very nearly in that position. To a spectator placed in any part of the extremity of that hemisphere, or what seems to us to be the margin of the moon, the earth will appear always nearly in the horizon; and to spectators at intermediate positions the earth will appear at higher or lower elevations above the horizon, according to their distance from the extremities or the central parts of that hemisphere. But, although the earth appears fixed nearly in the same part of the sky, there is a slight variation produced by what is termed the *libration* of the moon (see p. 87), by which it appears to turn occasionally a small portion of its hemisphere toward the earth. In consequence of this libration the earth will appear now and then to shift its position a little by a kind of vibratory motion, so that those at the extremities of the hemisphere, who see the earth in their horizon, will sometimes see it dip a little below, and at other times rise a little above their horizon. This vibratory motion they will probably be disposed, at first view, to attribute to the earth, which they will naturally consider as a body nearly at rest, but subject to a vibratory movement like that of a pendulum, whereas this apparent vibration proceeds from the moon itself.

The earth is continually shifting its *phases* as seen from the moon. When it is *new moon* to us it is *full moon* to the lunar inhabitants, as the hemisphere of the earth next the moon is then fully enlightened; so that, at the time when the sun is absent, they enjoy the effulgence of a full moon thirteen times larger than ours. When the moon is in the first quarter to us, the earth is in the third quarter to them; and, in every other case, the phases of the earth are exactly opposite to those which the moon presents to us (see p. 87). The earth passes through all the phases of the moon in the course of a month; but the *progress* of these phases will be more regularly and accurately perceived than that of the moon's phases are by us. When it is night in the moon, and the nights there are a fortnight long, the inhabitants see at first only a small part of the earth enlightened, like a slender crescent; then a larger and a larger portion, until at length it becomes entirely luminous. During the whole of these changes the earth is every moment visible, and apparently fixed in the same immovable position; and as there are no clouds in the lunar atmosphere, the view of the earth and of the variation of its phases will never be interrupted; whereas these changes in the moon are visible to us only from one night to another, and, by the interposition of clouds, the moon is frequently hidden from our view for seven or eight days together. By means of the light thus diffused by the earth upon the moon, it so happens that the side of the moon next the earth is never in darkness; for, when the sun is absent, the earth shines in the firmament with a greater or less degree of splendor; but when the sun is absent from the other hemisphere, the inhabitants have no light but what is derived from the stars and planets. It is probable, however, that the light of these luminaries is more brilliant as seen from the moon than from the earth; and as the lunar atmosphere is more pure and transparent than that of the earth, and as no clouds or dense vapors exist in it to intercept the rays of those distant orbs; and the stars and planets will constantly shine in the firmament of that hemisphere of the moon with undiminished luster.—Perhaps, too, there may be some arrangement for providing additional light to that hemisphere in the absence of the sun, either by the coruscations of some phosphoric substance, or by something analogous to our aurora borealis.

Whether the earth will throw as much light upon the moon, *in proportion to its size*, as the moon diffuses upon the earth, is somewhat doubtful. I am disposed to think that the greater part of the surface of the terraqueous globe will not reflect so much light, in proportion to its bulk, as the general surface of the moon; for, as the greater part of the earth is covered with water, and as water absorbs a considerable portion of the rays of light, the seas and ocean will present a more dark and somber aspect than any part of the lunar orb presents to us; but it is highly probable that the continents and islands will exhibit a luster nearly equal to that of the mountainous regions of the moon.

Although the earth will seem nearly fixed in one position, yet, *its rotation round its axis will be distinctly perceptible*, and will present a variety of different appearances. Europe, Asia, Africa, and America will present themselves one after another in different shapes, nearly as they are represented on our maps and globes; and the regions near our poles, which we have never yet had it in our power to explore, will be distinctly seen by the lunarians, who will be enabled to determine whether they chiefly consist of land or of water The several continents, seas, islands, lakes, peninsulas, plains, and mountain-ranges, will appear like so many spots, of different forms and degrees of brightness, moving over its surface. When the Pacific Ocean, which occupies nearly half the globe, is presented to view, the great body of the earth will assume a dusky or somber aspect, except toward the north, the north-east, and north-west; and the islands connected with this ocean will exhibit the appearance of small lucid spots on a dark ground. But when the eastern continent turns round to view, the earth (especially its northern parts) will appear to shine with a greater degree of luster. These appearances will be diversified by the numerous strata of clouds which are continually carried by the winds over different regions, and will occasionally intercept their view of certain parts of the continents and seas, or render their appearance more obscure at one time than at another. It is likewise probable that the occasional storms in tropical climates, and the changes produced in different countries by summer and winter, will cause the earth to present a diversity of aspect to the inhabitants of the moon. The bands of ice which surround the poles will alternately exhibit a kind of lucid circle, while the verdant plains will appear of a different color and assume a milder aspect. By means of these different spots, the lunarians will be enabled to determine the exact period of the earth's rotation, as we determine that of the sun by the appearance and disappearance of the spots on its surface. And as the period of the earth's rotation never varies, it may serve as a clock or dial for the exact measure of time; and the lesser divisions of this period may be ascertained by the appearance on the margin or the central parts of the earth's hemisphere of certain seas, continents, or large islands, which will constantly appear on certain parts of the earth's disc at regular intervals of time. Through telescopes such as ours, the variegated aspect of the earth in its diurnal motion would present to us, were we placed on the moon, a novel and most interesting appearance.

The apparent diurnal motions of the sun, the planets, and the stars, will appear much slower, and somewhat different in several respects from what they do to us. When the sun rises in their eastern horizon, his progress through the heavens will be so slow that it will require more than seven of our days before he comes to the meridian, and the same time before he descends to their western horizon; for the days and nights of the moon are nearly fifteen days each, and they are nearly of an equal length on all parts of its surface, as its axis is nearly perpendicular to the ecliptic, and, consequently, the sun never removes to any great distance from the equator. During the day the earth will appear like a faint cloudy orb, always in the same position; and during night the stars and planets will be visible, *without interruption*, for fifteen days, and will be seen moving gradually during that time from the eastern to the western horizon Though the earth will always be seen in the same point of the sky both by day and night, yet it will appear to be constantly shifting its position with respect to the planets and the stars, which will appear to be regularly moving from the east to the west of it, and some of them will occa sionally be hidden or suffer an *occultation* for three or four hours behind its body. The sun, planets, and fixed stars will appear exactly of the same apparent magnitudes as they do from the earth; but as the poles of the moon are directed to points of the heavens different from those to which the poles of the earth are directed, the pole-stars in the lunar firmament, and the stars which mark its equator and parallels, will all be different from ours; so that the stars, in their apparent diurnal revolutions, will appear to describe circles different from those which they describe in our sky. The *inferior* planets Mercury and Venus will generally be seen in the neighborhood of the sun, as they are from the earth; but they will be more distinctly perceived, and be visible for a much longer period of time after sunset than they are from our globe. This is owing, first, to the transparency of the lunar atmosphere, and the absence of dense vapors near the horizon, which, in our case, prevent any distinct observations of the celestial bodies when at a low altitude; and, secondly, to the slow apparent diurnal motion of these bodies. When Mercury is near its greatest elongation, it will remain above the horizon more than thirty hours after the sun has set, and, consequently, will be visible for a much longer time in succession than it is to us. When Venus is near its greatest elongation, it will be seen, without intermission, either as a morning or an evening star, for a space of time equal to more than three of our days. The *superior* planets, as with us, will be seen in different parts of the heavens, and occasionally in opposition to the sun; but they will appear to be continually shifting their positions with respect to the earth, and in the course of fifteen days will be seen in the very opposite quarter of the heavens, and in other fifteen days will be again in conjunction with the earth; and nearly the same appearances will be observed in reference to the other planets, but the periodic times of their conjunctions with the earth and oppositions to it will be somewhat different, owing to the difference of their velocities in their annual revolutions.

The *eclipses of the sun* which happen to the lunarians will be more striking, and total darkness will continue for a much longer time than with us. When a total eclipse of the *moon* happens to us, there will be a total eclipse of the *sun* to the lunarians. At that time the dark side of the earth is completely turned toward the moon, and the sun will appear to pass gradually behind the earth until it entirely disappears. The time of the continuance of *total darkness* in central eclipses will be nearly two hours; and, of course, a total eclipse of the sun will be a far more striking and impressive phenomenon to the inhabitants of the moon than to us. A complete darkness will ensue immediately after the body of the sun is hidden, and the stars and planets will be as clearly seen as at midnight. When a *partial* eclipse of the moon happens to us, all that portion of the moon's surface over which the shadow of the earth passes will suffer a *total* eclipse of the sun during the period of its continuance. On other parts of the moon's surface there will be a *partial* eclipse of the sun, and to those who are beyond the range of the earth's shadow no eclipse will appear. When an eclipse of the *sun* happens to us, the lunarians will behold a dark spot, with a penumbra or fainter shades around it, moving across the disc of the earth, which then appears a full enlightened hemisphere, excepting the obscurity caused by the progress of the shadow. The inhabitants on the other hemisphere of the moon can never experience a solar eclipse, as the earth can never interpose between the sun and any part of that hemisphere, so that they will only know of such phenomena by report, unless they undertake a journey for the purpose of observing them.

The study of astronomy in the moon will, on the whole, be more difficult and complex than to us on the earth. The phenomena exhibited by the earth will be the most difficult to explain. The lunarians, at first view, will be apt to imagine that the earth is a quiescent body in their firmament, because it appears in the same point of the sky, and that the other heavenly orbs revolve around it. It will require numerous observations of the apparent motions of the sun, the earth, the planets, and the stars, and numerous trains of reasoning respecting the phenomena they exhibit, before they are convinced that the globe on which they dwell really moves round the earth, and that both of them move, in a certain period, around the sun. If they are endowed with no higher powers than man, or if they are as foolish and contumacious as the great bulk of mankind, it will be more difficult to convince them of the true system of the world than it has been for our astronomers to convince a certain portion of our community that the earth turns round its axis, and performs a revolution round the sun. They will naturally think, as we did formerly, that their habitation is in a quiescent state in the center of the universe, and that all the other bodies in the heavens, except the earth, revolve around it; and the singular phenomena which our globe exhibits in their sky, with its diversified aspect, its diurnal rotation, and occasional *vibrations*, will puzzle them not a little in attempting to find out a proper explanation. It will be somewhat difficult for them to ascertain the exact length of their year or the time of their revolution round the sun. There are only two ways by which we can conceive they will be enabled to determine this point: 1. By observing when either of the poles of the earth begins to be enlightened and the other pole to disappear, which is always at the time of our equinoxes. 2. By observing the course of the sun among the stars, and endeavoring to ascertain when he returns to the same relative position in reference to any of these orbs. The length of the lunar year is about the same as ours, but different as to the number of days, the lunarians having only 12 7-19 days in their year, every day and night being as long as 29½ of ours. On the other hand, the lunar astronomers will enjoy some advantages in making celestial observations which we do not possess. Those who live on the side next the earth will be enabled to determine the *longitude* of places on the lunar surface with as much ease as we find the *latitude* of places on our globe. For as the earth keeps constantly over one meridian of the moon (or very nearly so), the east and west distances of places from that meridian may be readily found, by taking the altitude of the earth above the horizon, or its distance from the zenith, on the same principle as we obtain the latitude of a place by taking the altitude of the pole-star, or the hight of the equator above the horizon. The lunar astronomers will likewise possess advantages superior to ours in the purity of their atmosphere, and the greater degree of brilliancy with which the heavenly bodies will appear; and, in particular, they enjoy a singular advantage above a terrestrial astronomer in the *length of their nights*, which gives them an opportunity of contemplating the heavenly bodies, particularly Mercury and Venus, and tracing their motions and aspects for a length of time without intermission.

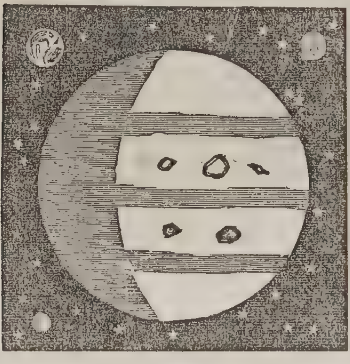
Such are some of the peculiar phenomena of the heavens as beheld from the moon. However different these phenomena may appear from those which are beheld in our terrestrial firmament, they are all owing to the following circumstances: that the moon moves round the earth as the more immediate center of its motion; that it turns always the same side to the earth, and, consequently, it moves round its axis in the same time in which it moves round the earth. These slight differences in the motions and relative positions of the earth and moon are the principal causes of all the peculiar aspects of the lunar firmament which we have now described. And this consideration shows us how the Creator may, by the slightest changes in the positions and arrangements of the celestial orbs, produce an indefinite variety of scenery throughout the universe, so that no world or system of worlds shall present the same scenery and phenomena as another. And so far as our knowledge and observation extends, this appears to be one of the grand principles of the Divine arrangements throughout the system of Creation, which will be still more apparent from the sketches I am now about to give of the phenomena presented from the surfaces of the satellites connected with the other planets.

The Scenery of the Heavens from the Satellites of Jupiter.—The scenery of the firmament as beheld from the satellites of this planet will bear a certain analogy to what we have now described in relation to the moon, but it will be much more diversified and resplendent. The most striking and glorious object in the firmament of the *first satellite* is the planet itself. The distance of this satellite from the center of Jupiter being only about three diameters of that body, it will appear in the heavens like an immense globe, above thirteen hundred times larger than the apparent size of our moon, and will occupy a considerable portion of the celestial hemisphere. To those who live in the middle of the hemisphere of this satellite, opposite to Jupiter, this vast globe will appear in the zenith, filling a large portion of the sky directly above them, equal to 19 degrees of a great circle, so that nine or ten of such bodies would reach from one side of the heavens to another. To those in other situations it will appear at different elevations above the horizon, according to their distances from the central parts of that hemisphere. This huge globe, in the course of twenty-one hours, will exhibit a crescent, a half moon, a gibbous phase, and a full enlightened hemisphere, so that its appearance will be perpetually changing. When it shines with a full face, it will exhibit a most glorious appearance; it will reflect an immense quantity of light upon the satellite, and all the varieties on its surface will be beautifully perceived. In the day-time it will present a cloudy appearance, continually changing its form, and when its dark side is turned to the satellite it will probably become invisible; but it will never be altogether invisible beyond two or three hours at a time, until its enlightened crescent again begins to appear. We find by the telescope that the surface of Jupiter is diversified with a variety of belts, which frequently change their appearance, and sometimes by bright and dark spots. Now all the varieties on its surface, and the changes which may take place in its atmosphere, will be pretty distinctly seen from the surface of this satellite; and as Jupiter turns round its axis in the space of less than ten hours, every hour will present a new scene upon its surface. This expansive and variegated surface of Jupiter, its diurnal rotation, and its rapid change of phases, will therefore form a most wonderful and interesting spectacle to the inhabitants of this satellite.

The three other satellites will likewise increase the variety and the luster of its firmament. The second satellite, in its course round Jupiter, will frequently come within 160,000 miles of the first, which is its nearest approach to it; at which time the satellite will appear with a face nearly three times as large as our moon. At other times it will be 680,000 miles distant, and will appear more than sixteen times smaller than in the former position. At the time when Jupiter presents its dark hemisphere to the first satellite, if the second satellite be then at its nearest distance, or in opposition to the sun, it will shine with a full enlightened hemisphere upon the first satellite. At other times it will assume a half moon, a crescent, or a gibbous phase; and these phases will not only be rapidly changing, but the apparent magnitude of the satellite will likewise be rapidly increasing or diminishing. While at one period it shines with a large and full enlightened face, in the course of two or three of our days it will appear as a slender crescent, and more than twelve or sixteen times less in apparent diameter than before. The third and fourth satellites will exhibit phenomena somewhat similar; but as their distance is greater than that of the second, their apparent magnitudes will be smaller, and the changes of their phases will be less frequent, in proportion to the slowness of their motions and the length of the periods of their revolutions. The eclipses of the sun, which so frequently happen to the first satellite from the interposition of the body of Jupiter, will form very interesting and impressive phenomena. Every forty-two hours this satellite suffers a solar eclipse for the space of more than two hours; and it is highly probable that it is chiefly at such times that the starry firmament appears in all its splendor, and affords its inhabitants an opportunity of tracing the motions and contemplating the phenomena of the distant bodies of the universe; for at other times the blaze of reflected light from the body of Jupiter and from the other satellites will, in all probability, prevent the greater part of the fixed stars from being distinctly perceived; so that these eclipses, instead of being an evil or a cause of annoyance to the inhabitants, will increase their enjoyment, will add to the variety of their celestial scenery, and open to them prospects of the grandeur of the starry firmament and the distant regions of creation.

What has been now stated in reference to the first satellite may also be applied in general to the other three satellites, with this difference, that Jupiter will appear of a different apparent magnitude from each satellite; and the motions, magnitudes, and aspects of the other satellites will likewise be somewhat different. In each satellite the great globe of Jupiter, suspended motionless in the sky, will be the most conspicuous object in the heavens. To the *second* satellite this globe will appear about 470 times larger than our moon; to the *third* 180 times; and to the *fourth* about 80 times the apparent size of the full moon. But each satellite will have certain other phenomena *peculiar to itself*, which it would be too tedious to describe. To all of them the occultations of the other satellites by the body of Jupiter; their eclipses by falling into its shadow; the varieties on its surface, caused by its diurnal rotation; the shadows of the satellites passing like dark spots across its disc; the transits of the satellites themselves, like full moons crossing the orb of Jupiter; the diversified phenomena of eclipses, some of them happening when the satellite is like a crescent or half moon, and some of them when it appears as a full enlightened hemisphere, and various other circumstances, will afford an indefinite variety of celestial phenomena; and scarcely a single day will pass in which some of these phenomena are not observed. The length of the day is different in each satellite. In the first satellite, the length of the day and night is 42 hours 27 minutes; in the second, 3 days, 13 hours; in the third, 7 days, 3½ hours; and in the fourth, 16 days, 16½ hours. The starry heavens will therefore appear to make a revolution round each satellite in these respective times. The other satellites will also appear to make a diurnal revolution, but in periods of time somewhat different. The variety of motions, and other phenomena to which we have now alluded, and particularly the rotation of Jupiter and the variation of its phases, will afford various accurate measures of time to all the satellites. The following figure contains a rude sketch of a portion of the firmament as it will appear from one of the satellites of Jupiter.

Fig. 111.



In this figure, suppose the larger circle at the top to represent one of the satellites as seen in the firmament of the fourth satellite, and suppose it appears with a surface twice the size of our moon; Jupiter would require to be double the size here represented, and more than fifteen times larger to represent its comparative size as viewed from the *first* satellite. The larger circle represents Jupiter when exhibiting a gibbous phase to the satellite; the three other figures are the other satellites under different phases.

Celestial Scenery of the Satellites of Saturn.—What has been stated above in relation to Jupiter's satellites will apply, in part, to those of Saturn. But the satellites of this planet have likewise celestial scenery *peculiar to themselves*, and the scenes presented to one satellite are, in some respects, different from those presented to all the rest. One of the most singular phenomena in their firmament is the diversified appearance of the body of Saturn, and that of its rings, which will be beheld in their sky under a great variety of aspects. To describe all the variety of phenomena peculiar to each satellite connected with Saturn would almost require a separate treatise, and therefore I shall state only two or three prominent facts in relation to the *first* and *seventh*, or the innermost and outermost satellites. The first satellite, being only 80,000 miles distant from the *surface* of Saturn and only 18,000 miles from the outer edge of the rings, the globe of Saturn and its stupendous rings must present a very august and striking appearance in its nocturnal firmament. The hemisphere of Saturn contains an area more than 1300 times larger than that of our moon; consequently, if the first satellite were placed at the same distance from Saturn as our moon, the surface of that planet would appear, from the satellite, 1300 times larger than the moon does to us. But the satellite is only 120,000 miles from the center of Saturn, or half the distance of the moon from the center of the earth; therefore Saturn will appear four times larger, or 5200 times greater, as seen from this satellite, than the moon when viewed from the earth. The moon occupies only the 1-90,000th part of our celestial hemisphere, but the globe of Saturn will fill *one-seventeenth part* of the visible firmament of its first satellite; and if we take the extent of the rings into account, they will occupy a space two or three times greater; so that the planet and its rings will present a most grand and magnificent object in the canopy of heaven, of which we can form only a very faint conception. It is not likely that more than one-half of the globe of Saturn will be visible from this satellite on account of the interposition of the rings; and as it moves in an orbit which is nearly parallel with the plane of the rings, the surfaces of these rings will be seen in a very *oblique direction;* but still they will exhibit a very resplendent appearance. When the *edge* of the exterior ring is opposite to the satellite, and enlightened by the sun, it will present a large arch of light in the heavens on each side of the planet, above which will appear half the hemisphere of Saturn. If the satellite turn round its axis in the same time in which it revolves round the planet, as is probable, Saturn and its rings will appear stationary in the heavens, and the planet will present to the inhabitants of the satellite a variety of phases, such as a half moon and a crescent, beside the variety of objects which will appear on the surface of Saturn during its rotation on its axis. The rings will likewise appear to vary their aspect during every revolution, beside the variety of objects they will present during their rotation. At one time they will exhibit large and broad luminous arches; at another time they will appear as narrow streaks of light; and at another they will appear like dark belts across the disc of Saturn. And as this satellite moves round the planet in the course of twenty-two and a half hours, these appearances will be changing almost every hour. The appearances of the six other satellites, continually varying their phases, their apparent magnitudes, and their relative aspects; their positions in respect to the body of Saturn and its rings; their occultations by the interposition both of the rings and the planet, and the eclipses to which they are frequently subjected, will produce a diversity of phenomena and a grandeur unexampled in the case of any other moving bodies in our system. The second satellite, when in opposition, or at its nearest position to the first, will be only thirty thousand miles distant; and although its real size is not greater than our moon, it will present a surface sixty-four times larger than the full moon does in our sky It will appear in all the phases of the moon in the course of less than thirty-six hours, and will be continually changing its apparent magnitude, on account of its removing farther from or nearer to the first satellite. The third satellite* will appear nearly half as large, as it is only seventy thousand miles distant at its nearest approach; and will present nearly the same varieties as the other.—All the other satellites will appear smaller in proportion to their distance from the orbit of the first; but they will all appear much larger than our moon, except the seventh, or outermost satellite, which will appear considerably smaller. Perhaps the sixth satellite from Saturn will not appear larger than our moon.

---

* Here the satellites are distinguished *according to the order of their distances from Saturn.*

The seventh or outermost satellite, which is reckoned among the largest, will have a scenery in its sky somewhat different from that of the first. As its orbit is materially inclined to the rings, its inhabitants will have a more ample prospect of these rings and of the body of Saturn than several of the other satellites, although these objects are beheld at a greater distance, and, consequently, will not fill so large a portion of its sky. Their appearance, however, will not be destitute of splendor; for this satellite is 400 times nearer Saturn than we are, and the body of this planet will appear sixteen times larger than the moon to us, and its rings will occupy a space proportionably more expansive. The phases of Saturn and its rings, and the various changes of aspect which they assume, will be more distinctly perceptible, though on a smaller scale, than from some of the interior satellites; for the whole body of the planet, as well as the rings, will in most cases appear full in view. The other six satellites will be seen in all the different phases and aspects above described, and they will never appear to recede to any great distance from the body of Saturn; but will appear first on one side and then on another, and sometimes either above or below the planet, as Mercury and Venus appear to us in respect to the sun, and, consequently, that portion of the heavens in which Saturn appears will present a most splendid appearance. In this respect the relative positions of the satellites, as seen from the outermost, will be different from their aspects and positions as viewed from the innermost satellite, where they will sometimes appear in regions of the sky directly opposite to Saturn. All the other satellites of this planet will have phenomena *peculiar to themselves* in their respective firmaments, and in all of them these phenomena will be exhibited on a scale of grandeur and magnificence. But to enter into details in reference to each satellite might prove tedious to the general reader.

Let us, then, conceive a firmament in which is suspended a globe five thousand times larger than the apparent size of our moon; let us conceive luminous arches, still more expansive, surrounding this globe; let us conceive six moons of different apparent magnitudes, some of them sixty times larger in apparent size than ours; let us conceive, further, all these magnificent bodies sometimes appearing in one part of the heavens and sometimes in another, changing their phases and apparent magnitudes and distances from each other every hour; appearing sometimes like a large crescent, sometimes like a small, sometimes shining with a full enlightened face, and sometimes suffering a total eclipse; sometimes hidden behind the large body of the planet, and sometimes crossing its disc with a rapid motion, like a circular shadow; let us suppose these and many other diversified phenomena presenting themselves with unceasing variety in the canopy of heaven, and we shall have some faint idea of the grandeur of the firmament as seen from some of the satellites of Saturn.

No delineations, except on a very large scale, could convey any tolerable idea of the objects now described. Fig. 112 exhibits a rude idea of the firmament as viewed from the first or second satellite of Saturn; but the body of Saturn and the ring should be eight or ten times larger in proportion to the size of the moons or satellites here represented. As the orbits of the inner satellites are nearly on the same plane as the rings, they will appear, in an oblique position, and it is questionable whether the division between the rings will be distinctly visible. The opposite part of the ring, or that which is most distant from the satellite, will appear smaller than the side which is nearest it; and only one-half of the body of Saturn will be seen, the other half being hidden, either in whole or in part, by the ring.

Fig. 112.

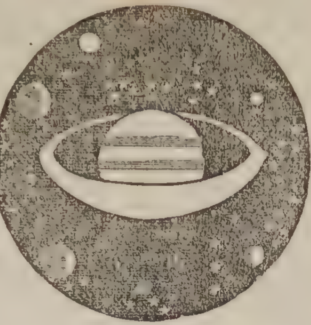


Fig. 113 represents the firmament of the seventh or outermost satellite. As its orbit is considerably inclined to the plane of the ring, the whole body of the planet will frequently be seen within the rings, which will appear as ovals around it. The six other satellites will appear in the vicinity of Saturn and its rings, none of them ever removing to any considerable distance from the edge of the rings, and some of them may occasionally be seen moving in the open space between the planet and the rings. In this figure Saturn and the rings should be considerably larger in proportion to the moons than they are here represented.

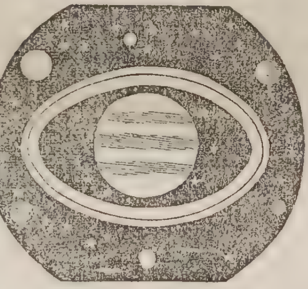
Fig. 113.



Celestial Scenery as viewed from the Rings *of Saturn.*—Supposing the rings to be inhabited, which there is as much reason to believe as that the planet itself is a habitable globe, it is probable that there is a greater diversity of celestial scenery and of sublime objects presented to view than any we have yet described. There will be at least six varieties of celestial scenery, according as the spectator is placed on different parts of the rings. One variety of scene will be exhibited from the *exterior* edge of the outer ring; a second variety from the *interior* edge of the inner ring; a third variety from the interior edge of the *outer* ring; a fourth from the exterior edge of the *inner* ring; a fifth from the *sides* of the rings enlightened by the sun; and a sixth variety from the opposite sides, which are turned away from the sun, and enjoy, for a time, only the reflected light from the satellites. To describe all these varieties in a minute detail would be tedious, and at the same time unsatisfactory, without the aid of diagrams and figures on a very enlarged scale, and therefore I shall chiefly confine myself to a general description of one of these celestial views.

Those who live on the sides of the rings will behold the one-half of the hemisphere of Saturn, which will fill, perhaps, the one-fifth or the one-sixth part of their celestial hemisphere, while the other portions of the planet will be hidden by the interposition of the rings. Those who are near the inner edge of the interior ring are only thirty thousand miles from the surface of Saturn, and consequently all the varieties upon its surface will be distinctly perceived. Those near the outer edge of the exterior ring are about sixty thousand miles distant from the planet, which will consequently appear to them four times less in size than to the former; but being only eighteen thousand miles from the first satellite at the time of its opposition to Saturn, that satellite will present an object more than three hundred and fifty times larger than our moon, which will rapidly assume different phases, and will be continually varying in its apparent magnitude; and at its greatest distance beyond the opposite side of the rings it will appear at least 170 times less than when in the nearest point of its orbit; and all the intermediate varieties of magnitude and aspect will be accomplished within less than two days. So that this satellite will be continually changing its apparent size, from an object two or three times the apparent bulk of our moon to one 350 times greater. The same may be affirmed in respect to the other six satellites, with this exception, that they will appear of a smaller magnitude, and the periodic times of their phases and the changes in apparent magnitude will be different.

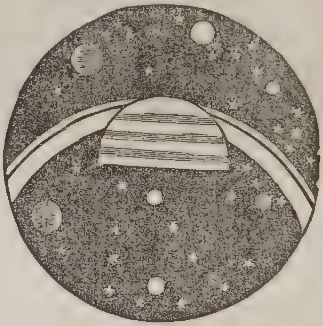
Another object which will diversify the firmament of those who are on one of the sides of the rings is the opposite portions of the rings themselves.—These will appear proceeding from each side of the planet like large broad arches of light, each of them somewhat less than a quadrant, and will fill a very large portion of the sky, so that the inhabitants of the same world will behold a portion of their own habitation forming a conspicuous part of their celestial canopy, and, at first view, may imagine that it forms a celestial object with which they have no immediate connection. Were they to travel to the opposite part of the ring, they would see the habitation they had left suspended in the firmament, without being aware that the spot which they left forms a portion of the phenomenon they behold. As the rings revolve round the planet, and the planet revolves round its axis, the different parts of the surface of the planet will present a different aspect, and its variety of scenery will successively be presented to the view. The eclipses of the sun and of the satellites, by the interposition of the body of Saturn and of the opposite sides of the rings, will produce a variety of striking phenomena, which will be diversified almost every hour.

From the dark side of the rings, which are turned away from the sun for fifteen years, a great variety of interesting phenomena will likewise be presented; and, during this period, the aspect of the firmament will in all probability be most vivid and striking. This portion of the rings will not be in absolute darkness during the absence of the sun, for some of the seven satellites will always be shining upon it; sometimes three, sometimes four, and sometimes all the seven, in one bright assemblage. It is probable, too, that the planet, like a large slender crescent, will occasionally diffuse a mild splendor; and, in the occasional absence of these, the fixed stars will display their radiance in the heavens, which will be the principal opportunity afforded for studying and contemplating these remote luminaries. Those who are on the outermost ring will behold the other ring, and the opposite parts of their own, like vast arches in the heavens; and although only 2800 miles intervene between the two rings, that space may be as impassable as is the space which intervenes between us and the moon.

If the two rings have a rotation round Saturn in different periods of time, as is most probable, it will add a considerable variety to the scenery exhibited by the different objects which will successively appear in the course of the rotation.

The numerous splendid objects displayed in the heavens, as seen from these rings, would afford a grand and diversified field for telescopic observations, surpassing in variety and sublimity whatever is displayed in any other region of the solar system; by which some of the objects might be contemplated as if they were placed within the distance of forty or fifty miles.

Fig. 114.



The preceding figure (114) represents a view of the firmament from one of the sides of the rings, in which is seen half of the hemisphere of Saturn, with a portion of the opposite sides of the rings projecting, as it were, from each side of the planet, the central part being hidden by the interposition of its body. From the inner edge of the interior ring the whole hemisphere of Saturn will be visible. The body of Saturn and the rings should be at least twenty times larger than here represented, so as to be proportionate to the apparent size of the satellites.

Celestial Scenery from the Satellites of Uranus.—After what we have stated respecting the satellites of Jupiter, it would be needless to enter into detail respecting the celestial views from the satellites of this planet, as they will bear a striking analogy to those of the moons of Jupiter; but the firmament of each satellite of Uranus will be more diversified than that of any of the satellites of Jupiter, as there are six satellites connected with this planet, and probably three or four more which lie beyond the reach of our telescopes.—From its first satellite the body of Uranus will appear nearly three hundred times larger than the apparent size of the moon in our sky, and, consequently, will appear a very grand and magnificent object in its firmament, while the other five moons, in different phases and positions, will serve both to illuminate its surface, and to diversify the scenery of the heavens. To the second satellite Uranus will appear about one hundred and eighty times larger than the moon to us; and to the other satellites it will present a smaller surface in proportion to their distance. Each satellite will have its own peculiarity of celestial phenomena; but after what we have already stated in the preceding descriptions, it would be inexpedient to enter into details. I shall therefore conclude these descriptions with the following remarks:

1. In the preceding descriptions, the *apparent magnitudes* of Jupiter, Saturn, and Uranus, as seen from the satellites, and the apparent magnitudes of the satellites, as seen from each other, are only approximations to the truth, so as to convey a *general idea* of the scenes displayed in their respective firmaments; perfect accuracy being of no importance in such descriptions. 2. The variety of celestial phenomena in the firmaments of these bodies is much greater than we have described.—Were we to enter into minute details in relation to such phenomena, it would require a volume of considerable size to contain the descriptions; for in the system of Saturn itself there is more variety of phenomena than in all the other parts of the planetary system. 3. Machinery would be requisite in order to convey clear ideas of some of the views alluded to in the preceding descriptions, particularly in relation to the rings and satellites of Saturn, in which the proportional distances and magnitudes of the respective bodies would require to be accurately represented. An instrument of considerable size and complication of machinery would be requisite for exhibiting all the phenomena connected with Saturn: and one of the principal difficulties would be to produce a diurnal rotation of the rings round Saturn, while at the same time they had no immediate connection with it, and while their *thickness* was no greater in proportion to their breadth than what is found in nature, which is only about the one three hundredth part of the breadth of the two rings, including the empty space between them. 4. The diversity of celestial scenery to which we have alluded is an evidence of the *infinite variety* which exists throughout the universe, and shows us by what apparently simple means this variety is produced. We are thus led to conclude, that among all the systems and worlds dispersed throughout boundless space, there is no one department of creation exactly resembling another. This is likewise exemplified in the boundless variety exhibited in our world, in the animal, vegetable, and mineral kingdoms. 5. The alternations of light and darkness, and the frequent eclipses of the celestial luminaries which happen among the bodies conected with Jupiter, Saturn, and Uranus, so far from being incoveniences and evils, may be considered as blessings and enjoyments; for it is only or chiefly when their inhabitants are deprived of the direct light of the sun, or its reflection from the satellites, that the starry heavens will appear in all their glory; and as the interval in which they are thus deprived of light is short, and as it adds to the variety of the celestial scene, it must be productive of pleasure and enjoyment. 6. The same planets will be seen in the firmaments of the satellites as in those of their primaries; but they will be seldom visible on account of the large portion of reflected light which will be diffused throughout their sky, except in those cases when their nocturnal luminaries suffer an occultation or a total eclipse. The bodies more immediately connected with their own system will form the chief objects of their attention and contemplation, and will appear more interesting and magnificent than any phenomena connected with more distant worlds. 7. On all the satellites, and particularly on the rings of Saturn, it will be more difficult to ascertain the true system of the universe than in any other point of the solar system. I have already alluded to the difficulty of determining the true system of the world as observed from the moon: but it will be still more difficult in the case of observers placed on the rings or satellites of Saturn. The numerous bodies which are seen every hour shifting their aspects and positions, the apparent complication of motions which they will exhibit, their phases, eclipses, and rapid diminution of apparent size, combined with the apparent diurnal revolution of the heavens and of all the bodies in their firmament, will require numerous and accurate observations, and powers of intellect superior to those of man, in order to determine with precision their place in the solar system and the true theory of the universe.

CHAPTER IX.

ON THE DOCTRINE OF A PLURALITY OF WORLDS, WITH AN ILLUSTRATION OF SOME OF THE ARGUMENTS BY WHICH IT MAY BE SUPPORTED.

In the preceding descriptions of the facts connected with the bodies which compose the planetary system, and of the celestial scenery displayed in their respective firmaments, I have assumed the position that they are all peopled with intellectual beings. This is a conclusion to which the mind is almost necessarily led, when once it admits the facts which have been ascertained by modern astronomers. It requires, however, a minute knowledge of the whole scenery and circumstances connected with the planetary system before this truth comes home to the understanding with full conviction. As in the preceding pages I have stated, with some degree of minuteness, the prominent facts connected with all the bodies of the solar system (except comets), so far as they are yet known, the way is now prepared for bringing forward a few arguments founded on these facts, which will require less extensive illustrations than if I had attempted to discuss this topic without the previous descriptions. It may be proper, however, to state, that in this volume I propose to bring forward *only a few* of those arguments or considerations by which the position announced above may be corroborated and supported, leaving the discussion of the remaining arguments to another volume, in which the other portions of the scenery of the heavens will be described. This is rendered almost indispensable on account of the size to which the present volume has already swelled.

SECTION I.

The first argument I shall adduce in support of the doctrine of a plurality of worlds is, that *there are bodies in the planetary system of such* MAGNITUDES *as to afford ample scope for the abodes of myriads of inhabitants.*

This position has been amply illustrated in the preceding parts of this volume, particularly in chapter iii. From the statements contained in chap. vi, it appears that the whole planetary bodies, exclusive of the sun, comprehend an area of more than *seventy-eight thousand millions of square miles*, which is *three hundred and ninety-seven times* the area of our globe; so that the surfaces of all the planets and their satellites are equal, in point of space, to 397 worlds such as ours. But as the greater part of our globe is covered with water, and, consequently, is unfit for the permanent residence of rational beings, and as we have no reason to believe that the other planets have such a proportion of water on their surface, if we compare the habitable parts of the earth with the extent of surface on the planets, we shall find that they contain *one thousand five hundred and ninety-five times* the area of all that portion of our globe which can be inhabited by human beings. If we take into consideration the *solid contents* of these globes, we find that they are more than *two thousand four hundred and eighty times* the bulk of our globe; and the number of inhabitants they would contain, at the rate of England's population, is no less than 21,895,000,000,000, or nearly *twenty-two billions*, which is more than *twenty-seven thousand times* the present population of our globe. In other words, the extent of surface on all the planets, their rings and satellites, in respect of space for population, is equivalent to 27,000 such worlds as ours in its present state.

Now, can we for a moment imagine that the vast extent of surface on such magnificent globes is a scene of barrenness and desolation; where eternal silence and solitude have prevailed, and will for ever prevail; where no sound is heard throughout all their expansive regions; where nothing appears but interminable deserts, diversified with frightful precipices and gloomy caverns; where no vegetable or mineral beauties adorn the landscape; where no trace of rational intelligences is to be found throughout all their wastes and wilds; and where no thanksgivings, nor melody, nor grateful adorations ascend to the Ruler of the skies? To suppose that such is the state of these capacious globes would exhibit a most gloomy and distorted view of the character and attributes of the Creator. It would represent him as exerting his creating power to no purpose; and as acting in a different, and even in an *opposite character*, in different parts of his dominions; as displaying wisdom in one part of his creation, and an opposite attribute in another. For, so far as we are able to penetrate, it appears demonstrable that matter exists chiefly, if not *solely*, for the sake of sensitive and intellectual beings; either to serve the purpose of gratifying the senses or of affording a medium of thought to the mental faculty, or of exhibiting to the mind a sensible display of the existence and perfections of the supreme Intelligence. And if it serve such purposes in this part of the creation which we occupy, reason says that it must serve similar purposes in other regions of the universe. How incongruous would it be to maintain that matter serves such purposes in our terrestrial sphere, and nowhere else throughout the range of the planetary system? In other words, that it is useful to sensitive existences within the compass of the *one four hundredth part* of that system, but serves no useful or rational purpose in the other three hundred and ninety-nine parts; for the area of the earth, as above stated, is only about the one four hundredth part of the area of all the other planets. Such a conclusion can never be admitted in consistency with those perfections which both natural and revealed religion attribute to the Deity. If matter was not created merely for itself, but for the enjoyment of a superior nature, then it necessarily follows, that *wherever matter exists, that nobler nature*, whether sensitive or intellectual, *for whose sake it was created, must likewise exist* throughout some portions of its extent. To replenish one comparatively little globe with sensitive and rational inhabitants, and to leave several hundreds empty, desolate, and useless, is the perfect reverse of art and contrivance, and altogether incompatible with the conceptions we ought to form of Him who is "the only wise God," and who is declared to have displayed himself, in all his operations, as "wonderful in counsel and excellent in working."

In accordance with this sentiment, we find the inspired writers, when speaking in the name of Jehovah, admitting the validity of such reasoning. "Thus saith Jehovah that created the heavens; God himself that formed the earth and made it: he hath established it; HE CREATED IT NOT IN VAIN; HE FORMED IT TO BE INHABITED. I am Jehovah, and there is none else."* Here it is plainly and pointedly declared, that to create the earth without the design of its being inhabited would have been a piece of folly inconsistent with the perfections of Him whose intelligence and wisdom are displayed throughout all his works. To have left it empty and useless would have been "to create it in vain." It would neither have contributed to the enjoyment of intellectual beings, nor served as a manifestation of the intelligence, wisdom, and beneficence of its Creator. This passage likewise intimates that it is the ultimate design of Jehovah that this world shall, ere long, be fully peopled with inhabitants, and that its forests and desolate wastes shall, in future ages, be transformed into scenes of beauty and fertility, fitted for being the abodes of renovated moral agents at that period when "the knowledge of the Lord shall cover the earth;" and this extension of population and of cultivation is evidently going forward with rapid progress at the present time in different quarters of the globe. In connection with this declaration respecting the earth, it is also declared, that the same Almighty Being that arranged the earth for the purpose of replenishing it with inhabitants, likewise "*created the heavens;*" plainly intimating, that as both the fabrics were erected by the same all-wise and omnipotent intelligence, the same wisdom is displayed in both, and that the same grand and beneficent designs are accomplished in the globes which roll in the heavens as well as in the constitution of the earth in which we dwell. If the one was created for *use*, for the enjoyment of rational natures, and as a theater in which the Divine perfection might be displayed, so was the other. It is added, "I am Jehovah, and there is none else;" implying that there is a *unity* of principle, design, and operation, in all his plans and arrangements throughout the universe, however different in the means employed, and however varied the effects produced in different parts of his dominions.

---

* Isaiah xlv. 18.

Some, however, may be disposed to insinuate that the Deity may have designs in view, in the creation of matter, of which we are altogether ignorant, and that the planets and other bodies in the heavens may display the Divine glory in some way or another, although they be not peopled with inhabitants. It is readily admitted that we are ignorant of many of the purposes of the Deity, of the details of his operations in the distant regions of creation, and of many of the plans and movements of his moral government; and that, through an eternal lapse of ages, we shall always remain in ignorance of some of the works and ways of the Almighty. But there are certain general principles and views with which the Deity evidently intends that all his rational creatures should be acquainted. It was evidently intended that the visible creation should *adumbrate*, as it were, the character of Him who produced it; or that it should serve as a mirror, in which His existence and some of His perfections might clearly be perceived. But if the great globes of the universe were destitute of inhabitants, how could the Divine glory be discovered in their structure? How could a confused mass of rubbish and desolation, however vast and extensive, display the intelligence, the wisdom, and the benevolence of its Maker? It might indicate a power surpassing our comprehension, but it would display no other perfection which tends to excite the admiration, the love, and the adoration of rational beings. Yet we are informed in the Scriptures that celestial intelligences celebrate the perfections of Jehovah, "because he hath created all things," and because they perceive "His works" to be "GREAT AND MARVELOUS." They ascribe to Him "wisdom, and glory, and honor, and power, and thanksgiving," from the display of His character which they perceive in his works. But how could they ascribe to him such perfections, if the mightiest of his works were a scene of barrenness and desolation. Wisdom can be attributed only where there appears to be a proportionating of *means* to *ends;* and goodness can have no place where there are no sensitive or rational beings to enjoy the effects of it. It is, therefore, a mere evasion to assert that the Divine glory may be manifested in the celestial globes, although destitute of inhabitants. Every part of the character of God, by which he is rendered amiable and adorable in the eyes of his intelligent offspring, would be obscured and distorted were we for a moment to harbor such a sentiment. For wherein does the Divine glory consist? It chiefly consists in the display of infinite wisdom, rectitude, holiness, and unbounded beneficence; and where such attributes are not manifested there cannot be said to be a display of Divine glory. But such attributes could never be traced by man, or by any other order of intelligences, were the planetary bodies and the other orbs of heaven a scene of eternal silence, solitude, and waste; where no percipient being existed to taste the goodness or to adore the perfections of its Creator.

SECTION II.

ARGUMENT II. *There is a* GENERAL SIMILARITY *among all the bodies of the Planetary System, which tends to prove that they are intended to subserve the same ultimate designs in the arrangements of the Creator.*

In the elucidation of this argument it will be requisite that a variety of facts, some of which have been noticed in the preceding pages, should be brought under review. We are not to imagine that the planets, considered as habitable worlds, are arranged exactly according to the model of our terrestrial habitation; for the Creator has introduced an infinite variety in every department of His works; and we know from observation that there are certain arrangements connected with those bodies which are very different from those which are found in connection with our globe. But in all worlds destined for the habitation of intellectual nature we should expect to find some general analogy or resemblance in their prominent features, and in those things which appear essential to the enjoyment of such beings. Were we to attend the dissection of any animal—a dog, for example—and perceive the heart, the stomach, the liver, the lungs, the veins, arteries, and other parts essential to life and enjoyment, we could scarcely doubt that the same organs, though perhaps somewhat modified, were likewise to be found in a cat, a bullock, or any other quadruped, and that they served the same purposes in all these animals. In like manner, when we find on our globe certain parts and arrangements essentially requisite to its being a habitable world, and when we likewise observe similar contrivances connected with other distant globes, we have every reason to conclude that they are intended to subserve similar designs. In accordance with this principle, I shall now proceed to detail a few contrivances and arrangements in the other planets, which evidently indicate that their grand and ultimate design is to afford enjoyment to sensitive and intellectual natures.

1. *All the planets*, both primary and secondary, *are of a spherical or spheroidal figure* similar to that of the earth. I have already shown (p. 103) that this figure is the most capacious and the best adapted to motion, both annual and diurnal, and that the greatest inconveniences would be produced were any world constructed of an angular figure. The only deviation from this figure is to be found in the rings of Saturn. But these rings are not angular bodies; for even the thin exterior edge of the rings is supposed, from some minute observations, to be curved; and, if so, it prevents the inconveniences which would arise from an angular construction. The flat sides of the rings, too, appear to have no angular elevations or protuberances more than what may be supposed from a gently-waving surface such as that of our globe• and although they are not globular bodies, they are *circular*, with thin edges, and are thus calculated for rapid motion along with the planet; and the flat sides, having no angular projections, appear perfectly adapted for being places of habitation, without any of those inconveniences or catastrophes which might ensue had they approximated to a cubical, prismatic, or pentagonal form. The rings, in short, approximate nearer to the globular figure and its conveniences than any other construction could have done, and show us that, although the Creator proceeds in his operations on some grand general principles, yet he is not limited or confined to one particular figure or

construction in arranging the celestial worlds. The planets, then, being all of a globular or circular form, appear completely adapted for being the abodes of living beings.

2. The planets are *solid bodies* similar to the earth. They are not merely a congeries of clouds and vapors formed into a globular shape, but possessed of weight, solidity, or gravity. This is evident from the dark and well-defined shadows which they throw on other bodies, and from the attractive influence they exert throughout the system. Their *figure* is a proof that they possess such qualities; for their roundness proceeds from an equal pressure of all their parts tending toward the same center. Nay, astronomers, by the aid of observation and mathematical calculations, can tell what are the relative gravities or weights of the different planets; what proportion, for instance, the gravitation of Jupiter or Saturn bears to that of our earth, and what influence their attractive power produces on their own satellites, on the motion of comets, and on the smaller and inferior planets. In consequence of this solidity and attractive power, all things connected with their surfaces are preserved in security and prevented from flying off to the distant regions of space; for it is this power, variously modified and directed, that preserves the material universe, and all the orders of beings connected with it, in compact order and harmony, without the influence of which all things in heaven and earth would soon be reduced to a universal chaos. In this respect, then, as well as in the former, the planets are fitted for the support of intellectual beings, furnished with material organs.

3. All the planets have an *annual revolution* round the sun. This revolution, in the case of the earth, combined with the inclination of its axis to the plane of its orbit, produces the variety of seasons; and although we are not to suppose that all the planets have seasons similar to ours, or that the heats of summer and the cold of winter are experienced in other worlds (see pp. 44, 45), yet there is a certain variety of scene produced by this revolution in all the planets, particularly in those which have their axes of rotation inclined more or less to the plane of their orbits. This variety of scene will be particularly experienced on Saturn and on the surface of its rings; for in the course of one-half of the annual revolution the sun will shine on certain parts of these bodies, and during the other half they will be deprived of his direct influence. The annual revolutions of the planets, therefore, appear expedient, in order to produce an agreeable interchange and variety of scenes, for the purpose of gratifying their inhabitants. The periods of these revolutions, too, are adjusted with the utmost exactness. The planets perform their circuits without deviating in the least from the paths prescribed, and finish their revolutions exactly in the appointed time, so as not to vary the space of a minute in the course f centuries. Now, were these bodies merely extensive regions of uncultivated deserts, or were they placed in the vault of heaven merely that a few terrestrial astronomers might peep at them occasionally through their glasses, it is not at all likely that so much care and accuracy would have been displayed in marking out their orbits and adjusting their motions and revolutions.

4. The planets perform *a diurnal rotation* round their axes. This has been ascertained in reference to Venus, Mars, Jupiter, and Saturn, and we may justly conclude, from analogy, that the same is the case in respect to all the other planets. Wherever spots have been discovered on the surface of any planet, it has uniformly been found to have a diurnal rotation. But where no spots or prominences have been observed, it is obvious that no such motion, though it really exist, can be detected. No spots have been observed on the planet Mercury, on account of its smallness and its proximity to the sun; nor on the planet Uranus, on account of its very great distance from the earth; but there can be no doubt whatever that they have a diurnal motion as well as the other planets. By this motion every part of their surface is turned in succession toward the sun, and the alternate changes of day and night are produced. Were no such motion existing, one-half of these globes would be entirely uninhabitable, for the enlivening rays of the sun would never cheer its desolate regions, and the other half might be dazzled or parched with heat under the perpetual effulgence of the solar beams. Beside, the continuance of a perpetual day, and the illumination of the sky by an uninterrupted efflux of solar light, would prevent the distant regions of creation from being seen and contemplated, so that no body, except the sun himself, and the planet on which the spectator stood, would be known to exist in the universe. But it appears to have been the intention of the Creator not only to cheer the planets by the invigorating influence of the sun, but likewise to open to the view of their inhabitants a prospect into the regions of distant worlds, that they may behold a display of his wisdom and omnipotence, and of the magnificence of his empire; and this object has been completely effected in every part of the system by impressing upon the planets a motion of rotation, so that there is no body within the range of the solar influence that does not, at one period or another, enjoy this advantage.

The idea of night among the celestial bodies ought not to be associated with gloom, and darkness, and deprivation of comforts. In our world this is frequently the case. A cloudy atmosphere, combined with the fury of raging winds, hurricanes, and the appaling thunder-storm, frequently renders our nights a scene of gloom and terror especially to the benighted traveler and the mariner in the midst of the ocean. But such gloomy and terrific scenes would never have taken place had our globe and its inhabitants remained in that state of order and perfection in which they were originally created; and, therefore, we are to consider such physical evils as connected with the *moral state* of the present inhabitants of the earth. But even here, amid the gloom and darkness which frequently surround us, *night* not unfrequently opens to view a scene of incomparable splendor and magnificence; a scene which, were it confined to one quarter of the globe, millions of spectators would be eager to travel thousands of miles in order to behold it. In a clear and serene sky, night unfolds to us the firmament, bespangled with thousands of stars, twinkling from regions immensely distant, and the planets revolving in their different circuits, all apparently moving around us in silent grandeur. When the moon appears amid the host of stars, the scene is diversified and enlivened. Poets and philosophers in all ages have been charmed and captivated with the mild radiance of a moonlight scene, which partly unvails even the distant landscape, and throws a soft luster and solemnity both on earth and sky altogether different from their aspect under the meridian sun. But we have already shown (chapter viii) that the splendor of the heavens during night in some of the other planets is far more magnificent and diversified than what is exhibited in our firmament. The nocturnal scenes in the heavens of Jupiter, Saturn, Uranus, and their rings and satellites, in point of sublimity and variety, exceed every conception we can now form of celestial grandeur and magnificence; and, therefore, it is highly probable, that in those regions the scenes of night will be far more interesting and sublime, and will afford objects of contemplation more attractive and gratifying than all the splendors of their noonday. In this rotation of the planetary orbs there is a striking display both of wisdom and goodness, in causing a means so apparently simple to be productive of so rich a variety of sublime and beneficent effects; and this circumstance of itself affords a strong presumptive evidence that every globe in the universe which has such a rotation is either a world peopled with inhabitants, or connected with a system of habitable worlds; for, without such a motion, the one-half, at least, of every globe would be unfit for the residence of organized intelligences. It is not improbable that most, if not all the globes of the universe have a diurnal rotation impressed upon them. We find that even the globe of the sun has a motion of this kind, which it performs in the course of twenty-five days; and the phenomena of variable stars have induced some astronomers to conclude that their alternate increase and diminution of luster is owing to a motion of rotation around their axes.

5. All the planets and their satellites are *opaque bodies*, which derive their luster from the sun. That Venus and Mercury are opaque globes, which have no light in themselves, is evident from their appearing sometimes with a gibbous phase, and at other times like a crescent or a half moon; and particularly from their having been seen moving across the disc of the sun like round black spots. Mars being a superior planet, can never appear like a crescent or a half moon; but at the time of its quadrature with the sun it assumes a gibbous phase, somewhat approaching to that of a half moon, which likewise prove that it is an opaque globe. Jupiter and Saturn must always appear round, on account of their great distance from the earth; but that Jupiter is opaque appears from the dark shadows of his satellites moving across his disc when they interpose between him and the sun; and that Saturn is likewise a dark body of itself appears from the shadow of the rings upon its disc. That the moon has an opaque body has been already shown (p.88), and it is obvious to almost every observer; and that the satellites of Jupiter and Saturn are opaque appears from their eclipses, and the shadows they project on their respective planets. In this respect both the primary and the secondary planets are bodies analogous to the earth, which is likewise opaque, and derives its light either directly from the sun or by reflection from the moon, except the feeble rays which proceed from the stars. It forms, therefore, a presumptive argument that all these bodies have a similar destination; for we cannot conceive any other globe so well fitted for the habitation of rational beings as that which is illuminated by light proceeding from another body. An inherent splendor on the surface of any globe would dazzle the eyes with its brilliancy, and could never produce such a beautiful diversity of form, shade, and coloring as appears on the landscapes of the earth, by means of the reflections of the solar rays. And therefore, if the sun be inhabited, it can only be its dark central nucleus, and not the exterior surface of its luminous atmosphere.

6. The bodies belonging to the planetary system *are all connected together by one common principle or law*, namely, the law of gravitation. They are all subject to the attractive influence of the great central luminary; they revolve around it in conformity to the general law, that the squares of their periodical times are proportional to the cubes of their distances; they describe equal areas in equal times; their orbits are elliptical; they are acted upon by centripetal and centrifugal forces; and they all produce an attractive influence on each other, in proportion to their distances and the quantity of matter they contain Being thus assimilated and combined into one harmonious system, the presumption is, that, however different in point of distance, magnitude, and density, they are all intended to accomplish the same grand and beneficent design, namely, to serve as the abodes of living beings, and to promote the enjoyment of intellectual natures.

Since the planets, then, are all similar to one another in their spherical or spheroidal figures; in their being solid and opaque globes; in their annual and diurnal revolutions; and in being acted upon by the same laws of motion; and since these circumstances are all requisite to the comfort and enjoyment of living beings, it is a natural and reasonable conclusion that their ultimate destination is the same, and that they are all replenished with inhabitants. This earth on which we dwell is one of the bodies possessed of the qualities and arrangements to which we allude; and we know that its chief and ultimate design is to support a multitude of sensitive and intellectual beings, and to afford them both physical and mental enjoyment. Had not this been its principal destination, we are assured, on the authority of Divine revelation, that "*it would have been created in vain.*" We must therefore conclude that all the other globes in our system were destined to a similar end, unless we can suppose it to be consistent with the perfections of Deity that they were created for no purpose.

SECTION III.

ARGUMENT III. *In the bodies which constitute the solar system, there are* SPECIAL ARRANGEMENTS *which indicate their* ADAPTATION *to the enjoyments of sensitive and intelligent beings; and which prove that this was the ultimate design of their creation.*

This argument is somewhat similar to the former; but it may be considered separately, in order to prevent an accumulation of too many particulars under one head.

1. The surfaces of the plains *are diversified with hills and valleys, and a variety of mountain scenery.* This is particularly observable in the moon, whose surface is diversified with an immense variety of elevations and depressions, though in a form and arrangement very different from ours (see pp. 88–91). It cannot be ascertained by direct observation that there are mountains on the surfaces of Jupiter, Saturn, or Uranus, by reason of their great distances from the earth. But that they are rough or uneven globes appears from their reflecting the light to us from every part of their surfaces, and from the spots and differences of shade and color which are sometimes distinguishable on their discs. For if the surfaces of the planets were perfectly smooth and polished, they could not reflect the light in every direction; the reflected image of the sun would be too small to strike our eyes, and they would consequently be invisible. (See p. 88.)

Indications of mountains, however, have been seen on some of the other planets, particularly on Venus. Spots have been observed on this planet on different occasions, and the boundary between its dark and enlightened hemisphere has appeared jagged or uneven, a clear proof that its surface is diversified with mountains and vales. One of these mountains was calculated by Schroeter to be nearly eleven, and another twenty-two miles in perpendicular elevation; and there can be but little doubt that such inequalities are to be found on the surfaces of all the planets and their satellites, although they are not distinctly visible to us on account of their distance.

The existence of *mountains* on the planets is therefore a proof, or, at least, a strong presumptive evidence, that they are habitable worlds; for a perfectly smooth globe could present no great variety of objects or picturesque scenery, such as we behold in our world, and would doubtless be attended with many inconveniences. The view from any point of such a globe would be dull and monotonous, like the expanse of the ocean, or like the deserts of Zahara or Arabia. It is the beautiful variety of hills and dales, mountains and plains, and their diversity of shadows and aspects, that render the landscapes of the earth interesting and delightful to the painter, the poet, the man of taste and the traveler. Who would ever desire to visit distant countries, or even distant worlds, if they consisted merely of level plains, without any variety, of several thousands of miles in extent? The mountains add both to the sublimity and the beauty of the surface of our globe; and from the summits of lofty ranges the most enchanting prospects are frequently enjoyed of the rivers and lakes, the hills and vales, which diversify the plains below. But beside the beauty and variety which the diversity of surface produces, mountains are of essential *use* in the economy of our globe. They afford many of the most delightful and salubrious places for the habitations of man; they arrest the progress of stormy winds; they serve for the nourishment of animals, and the production of an infinite variety of herbs and trees; they are the depositories of stones, metals, minerals, and fossils of every description, so necessary for the use of man; and they are the portions of the globe where fountains have their rise, and whence rivers are conveyed to enliven and fertilize the plains. For, if the earth were divested of its mountains, and every part of its surface a dead level, there could be no running streams or conveyance for the waters, and they would either stagnate in large masses or overflow immense tracts of land. Hence it has been arranged by the wisdom of Providence that mountains should exist over all our globe, and that every country should enjoy the numerous benefits which such an arrangement is fitted to produce.

As mountains, then, are part of the arrangements of other globes in the solar system, and as they are essentially requisite in such a world as ours, they may serve similar and even more important purposes in other worlds. In some of the planets they appear to be more elevated and of greater dimensions than on the earth. Although the moon is much less in size than our globe, yet some of its mountains are reckoned to be five miles in perpendicular hight. Some of the mountains on Venus are estimated to be four times higher than even this elevation. We may easily conceive what an extensive and magnificent prospect would be presented from the top of such sublime elevations, and what a diversity of objects would be presented to the eye from one point of view. Nor need we imagine there will be any great difficulty in ascending such lofty eminences, for the inhabitants of such worlds may be furnished with bodies different from those of the human race, and endowed with locomotive powers far superior to ours. If, therefore, the planets were found to be perfectly smooth globes, without any elevations or depressions, we should lose one argument in support of their being designed for the abodes of rational beings; but having the characteristic now stated, when taken into consideration with other arguments, it corroborates the idea of their being habitable worlds.

2. The planets, in all probability, are environed with *atmospheres*. It appears pretty certain that the moon is surrounded with such an appendage (see pp. 93, 94). The planet Mars is admitted by all astronomers to be environed with a pretty dense atmosphere, which is the cause of its ruddy appearance (see pp. 49, 50); and indications of an atmosphere have been observed on Venus and some of the other planets. To our world an atmosphere is a most essential appendage. Without its agency our globe would be unfit for being the residence of living beings constituted as they now are; and were it detached from the earth, all the orders of animated nature, and even the vegetable tribes would soon cease to exist. Atmospheres somewhat analogous to ours may likewise be necessary in other worlds. But we have no reason to conclude that they are exactly similar to ours. While our atmosphere consists of a compound of several gaseous substances, theirs may be formed of a pure homogeneous ethereal fluid, possessed of very different properties. While ours is impregnated with dense vapors, and interspersed with numerous strata of thick clouds, the atmosphere of some of the other planets may be free of every heterogeneous substance, and perfectly pure and transparent. Their reflective and refractive powers, and other qualities, may likewise be different from those of the atmosphere which surrounds the earth. Hence the folly of denying the existence of an atmosphere around the moon or any other planet, because a fixed star or any other orb is not rendered dim or distorted when it approaches its margin. For if its atmosphere be either of small dimensions, or perfectly pure and transparent, or of a different refractive power from ours, such a phenomenon cannot be expected. We have no more reason to expect that the atmospheres of other planets should be similar to ours, than that these bodies should be of the same size, have the same diversity of objects on their surface, or be accompanied with the same number of moons.

It is not likely that our atmosphere is precisely in the same state as at the first creation. Its invigorating powers had then an influence sufficient to prolong human existence to a period of a thousand years; but, since the change it underwent at the deluge, the period of human life has dwindled down to little more than "threescore years and ten." The present constitution of our atmosphere, therefore, ought not to be considered as a model by which to judge of the nature and properties of the atmospheres of other worlds. Their atmospheres may be so pure and transparent as to enable their inhabitants to penetrate much farther into space than we can do, and to present to them the heavenly bodies with more brilliancy and luster; and the properties with which they are endowed may be fitted to preserve their corporeal organs in undecaying vigor, and to raise their spirits to the highest pitch of ecstasy, similar to some of the effects produced on our frame by 'nhaling that gaseous fluid called the *nitrous oxide*. There is only one planet whose atmosphere appears to partake of the impurity and density of that of the earth, and that is the planet Mars; and several other circumstances tend to show that it bears too near a resemblance to our globe. In this respect, then, it gives indication of being a habitable world; but several of the other planets may be abodes of greater happiness and splendor, although no traces of such an appendage can be distinguished by our telescopes. And this very circumstance, that their atmospheres are invisible, should lead us to conclude that they are purer and more transparent than ours, and that the moral and physical condition of their inhabitants is probably superior to what is enjoyed upon earth.

3. There is provision made *for the distribution of light, and heat, and color* among all the planets and their satellites. On every one of these bodies the sun diffuses a radiance, and, in order that no portion of their surfaces may be deprived of this influence, they appear all to have a motion round their axes. *Light* is an essential requisite to every world, and *color* is almost equally indispensable. Without color we should be unable to perceive the forms, proportions, and aspects of the objects which surround us; we could not distinguish one object from another; all the beauties, varieties, and sublimities of nature would be annihilated, and we should remain destitute of the noblest entertainments of vision. It is color which enlivens every scene of nature, which adds a charm to every landscape, and gives an air of beauty and magnificence to the spacious vault of heaven. Now color exists in the solar rays, without which, or some similar radiance, every object is either invisible or wears a uniform aspect. On whatever object these rays fall, color is produced; they have the same properties in every part of the system as on our globe, and, therefore, must produce colors of various hues on the objects connected with the remotest planets, according to the nature of the substances on which they fall. Light and color, then, being essential to every globe intended for the habitation of living beings, abundant provision has been made for diffusing their benign influence through every part of the planetary system. Heat is likewise an agent which appears necessary to every world, and it is, doubtless, distributed in due proportions throughout the system, according to the nature of the substances of which the planets are composed, and the constitution of their inhabitants. But light, and color, and heat are agencies which can only have an ultimate respect to sensitive and intellectual beings; and, therefore, where no such beings exist or are intended to exist, no such provision would be made by a wise and intelligent agent. Such care as appears to have been taken for the communication of the agencies of light, heat, and color, would never have been exercised for the sake of rocks and deserts, and scenes of sterility and desolation. The existence of *light*, with all the enchanting effects it produces, necessarily supposes the existence of *eyes*, in order to enjoy its beneficial influence; and, therefore, organized beings, endowed with *visual organs*, must exist in all those regions where contrivances have been adapted for its regular and universal diffusion; otherwise the universe might have remained a scene of eternal darkness.

4. The principal primary planets are *provided with secondary planets or moons*, to afford them light in the absence of the sun, as well as to accomplish other important purposes. The three largest planets of the system are accommodated with no fewer than *seventeen* of those nocturnal luminaries, and probably with several more which lie beyond the reach of our telescopes. Our earth has one; and it is not improbable that both Mars and Venus are attended by at least one satellite. These attendants appear to increase in number in proportion to the distance of the primary planet from the sun. Jupiter has four such attendants; Saturn, seven; six have been discovered around Uranus; but the great difficulty of perceiving them, at the immense distance at which we are placed, leads to the almost certain conclusion that several more exist which have not yet been detected. While these satellites revolve round their respective planets, and diffuse a mild radiance on their surfaces in the absence of the sun, they also serve the same purposes to one another; and their primaries, at the same time, serve the purpose of large resplendent moons to every one of their satellites, beside presenting a diversified and magnificent scene in their nocturnal sky. No satellite has yet been discovered attending the planet Mercury, nor is it probable that any such body exists. But we have already shown (pp. 114, 115) that Venus and the earth serve the purposes of satellites to this planet, Venus sometimes appearing six times as large, and the earth two or three times as large as Venus does to us at the period of its greatest brilliancy; so that the nights of Mercury are cheered with a considerable degree of illumination. Here, then, we perceive an *evident design* in such arrangements, which can have no other ultimate object in view than the comfort and gratification of intelligent beings. For a retinue of moons, revolving around their primary planets at regular distances and in fixed periods of time, would serve no useful purpose in throwing a faint light on immense deserts, where no sensitive beings, furnished with visual organs, were placed to enjoy its benefits; nor, if this were the case, is it supposable that so much skill and accuracy would have been displayed in arranging their distances and their periodical revolutions, which is accomplished with all the accuracy and precision which are displayed in the other departments of the system of nature.

The *small density* of the larger and more remote planets, and *the diminution of the weight of bodies on their surfaces* on this account, and by their *rapid rotation* on their axes, appear to be instances of design which have a respect to sentient beings. The density of Jupiter is little more than that of water, and that of Saturn about the density of cork. Were these planets as dense as the planet Mercury, or had they even the density of the earth, organized beings like man would be unable to traverse their surfaces. If the density of Jupiter, for example, were as great as that of the earth, the weight of bodies on its surface would be eleven times greater than with us; so that a man weighing 160 pounds on the earth would be pressed down on the surface of Jupiter with a force equal to one thousand seven hundred and sixty pounds. But the gravity of bodies on the surface of this planet is only about twice as great as on the surface of the earth; and *this gravitating power is diminished by its rapid rotation on its axis*. For the centrifugal force which diminishes the weight of bodies is *sixty-six* times greater on Jupiter than on the earth, and will relieve the inhabitants of one-eighth part of their weight, which they would otherwise feel if there were no rotation; so that a body weighing 128 pounds if the planet stood still, would weigh only 112 pounds at its present rate of rotation, which will afford a sensible relief and diminution of weight (see p. 59, Art. *Jupiter*). The same may be said, with some slight modifications, in relation to Saturn. There must, therefore, have been a *design*, or a wise and prospective contrivance in such arrangements, to suit the exigencies and to promote the comfort of organized intelligences; otherwise, had Jupiter and Saturn been as much denser than the earth as they are lighter, every body would have been riveted to their surfaces with a force which beings like man could never have overcome; and moving beings with such organical parts as those of men would have had to drag along with them a weight of eight or ten thousand pounds.

In the preceding statements I have endeavored to show that there is a *general similarity* among all the bodies of the planetary system, and that there are *special arrangements* which indicate their *adaptation* to the enjoyment of sensitive and intellectual beings. Let us now consider more particularly the force of the argument derived from such considerations:

That the Divine Being has an *end* in view in all his arrangements, and that this end is in complete correspondence with his infinite wisdom and goodness, and the other perfections of his nature, is a position which every rational Theist will readily admit. That some of the prominent designs or general ends which the Deity intended to accomplish may be traced in various departments of his works, is likewise a position which few or none will deny. That design may be inferred from its effects, is a principle which mankind generally recognize in their investigations of the operations both of nature and of art. That man would justly be accused of insanity who, after inspecting the machinery of a well-constructed clock, and perceiving that it answered the purpose of pointing out the divisions of time by hours, minutes, and seconds with the utmost accuracy, should *deny* that its various parts were formed and arranged for the very purpose which the machine so exactly fulfills; at least, that the pointing out of the hours and minutes was one of the main and leading objects which the artist had in view in its construction. It is a law of our nature which we cannot resist, that from the effect the design may be inferred; and that, wherever art or contrivance appears exactly adapted to accomplish a certain end, that end was intended to be accomplished. We cannot doubt for a moment of the final causes of a variety of objects and contrivances which present themselves to view in the world we inhabit. We cannot err in concluding, for example, that the ears, legs, and wings of animals were made for the purpose of hearing, walking, and flying. On the same principle we are led to conclude, that as animals are formed with mouths, teeth, and stomachs to masticate and digest their food, so vegetables and other organized bodies were formed for the purpose of affording that nourishment which the animal requires. No one will take upon him to deny that the eye was intended for the purpose of vision. The coats and humors of which it is composed, and the muscles which move it in every direction, in their size, shape, connection, and positions, are so admirably adapted to this end, and the transparency of the *cornea*, and the *humors*, the opacity of the *uvea*, and the semi-opacity and concavity of the *retina*, are so necessary to transmit and refract the rays of light in order to distinct vision, that it appears as evident it was designed for this purpose, as that telescopes were constructed to discover the colors, shapes, and motions of distant objects. And as the eye was constructed of a number of nice and delicate parts for the purpose of vision, so light was formed for the purpose of acting upon it and producing the intended effect, without the agency of which vision could not be produced. The one is exactly adapted to the other; for no other substance but light can affect the eye so as to produce vision, and no other organ of sensation is susceptible of the impressions of light, so as to convey a perception of any visible object. In all such cases, the adaptation of one contrivance to another, and the intention of the Contriver, are quite apparent.

It is true, indeed, that we cannot pretend to explore *all the ends or designs* which God may have had in view in the formation of any one object or department of the universe. For an eternal and omniscient Being, whose wisdom is unsearchable, and whose eye penetrates through all the regions of immensity, may have subordinate designs to accomplish, which surpass the limited faculties of man, or even of angels, to comprehend. But to investigate and to perceive *some* of the main and leading ends which were designed in the arrangement of certain parts of the universe, is so far from being presumptuous and unattainable, that it would be blindness and folly in a rational creature not to discover them; particularly in such instances as those to which we have now alluded. For it appears to be the intention of the Deity, in displaying his works to intelligent minds, that these works shall exhibit a manifestation of his attributes, and particularly of his wisdom, goodness, and intelligence; and he has endowed them with faculties adequate to enable them to perceive some traces of his footsteps and of the plan of his operations. But while he permits us to perceive some of the grand lineaments of his designs, there may be numberless minute and subordinate ends which lie beyond the sphere of our investigations. Were a peasant brought into the observatory of an astronomer, and shown an instrument calculated to point out the sun's place in the ecliptic, its declination and right ascension, the day of the month, &c., and particularly the *hour* of the day, it would be presumptuous in such a person to pretend to ascertain *all* the intentions of the artist, or all the uses for which such a machine was constructed; but when he beheld the ordinary marks of a sun-dial, and the shadow of the gnomon accurately pointing to the hour, he could not fail at once to perceive that this was *one* principal end which the contriver had in view. In like manner, while we evidently perceive that one principal design of the creation of the sun was to enlighten the earth and other bodies which move around it, it also serves several subordinate purposes. It directs the course of winds, promotes evaporation and the growth of vegetables; it retains the planets in their orbits; it kindles combustible substances by means of convex glasses and concave mirrors; it enables us to measure time by means of dials; it directs the geographer to determine the elevation of the pole and the latitude of places; it guides the navigator in his course through the ocean, and even its eclipses serve many useful purposes, both in chronology and astronomy; and it may serve similar or very different purposes with which we are unacquainted, among the inhabitants of other worlds. All these purposes, and many more of which we are ignorant, may have entered into the designs of the almighty Creator, although, in the first instance, we might have been unable to discover or appreciate them. As "the works of the Lord are great," so they must "be sought out," or diligently investigated, in order that we may clearly perceive the manifold designs of infinite wisdom.

Let us now apply these principles to the subject more immediately before us. We have seen that, in the distant bodies of our system, there are special contrivances and arrangements, all calculated to promote the enjoyment of myriads of intelligent agents. We have presented before us a most august and astonishing assemblage of *means;* and if the Contriver of the universe is possessed of wisdom, there must be an *end* proportionate to the utility and grandeur of the means provided. Arrangements nearly similar, but much inferior in point of extent and magnificence, have been made in relation to the globe on which we live. We know the final cause, or, at least, one of the principal designs for which it was created, namely, to support sensitive and intellectual beings, and to contribute to their enjoyment. If, then, the Creator acts on the same principle—in other words, if he displays the same intelligence—in other regions of the universe as he does in our world, we must admit that the planetary globes are furnished with rational inhabitants. There is one essential attribute which enters into all our conceptions of the Divine Being, namely, *that he is possessed of infinite wisdom.* This perfection of his nature is displayed in all the general arrangements he has made in this lower world, where we find one part nicely adapted to another, and everything so balanced and arranged as to promote the comfort of sentient beings. In consequence of His being possessed of this perfection, He must be considered, in *all* His operations throughout the immensity of space, as proportionating the means to the end, and selecting the best means possible for the accomplishment of any design; for in such contrivances and operations true wisdom consists.

But now let us suppose for a moment that the vast regions on the surfaces of the planets are only immense and frightful deserts, devoid of inhabitants; *wherein does the wisdom of the Creator appear on this supposition?* For what purpose serves the grand apparatus of rings and moons for adorning their sky and reflecting light on their hemispheres? Why are they made to perform annual and diurnal revolutions, and not fixed in the same points of infinite space? Why are the larger and remoter planets furnished with more moons than those which are nearer the source of light? Why are their firmaments diversified with so many splendid and magnificent objects? Why is their surface arranged into mountains and vales? Why has so much contrivance been displayed in devising means for the illumination of every portion of their surfaces, and diffusing over them a variety of colors? The answers to such questions would, then, be, to illuminate an immense number of dreary wastes, and to produce days and nights, and a variety of seasons, for the sole benefit of interminable deserts, or, at most, of mountains of marble or rocks of diamonds; to afford them light enough to see to keep their orbits, lest they might miss their way in the pathless spaces through which they move! Is such an apparatus requisite for such a purpose? *Would this be an end worthy of* INFINITE WISDOM? Would it at all correspond with the dignity and grandeur of the means employed? Would it comport with the boundless intelligence of Him "who formed the earth by his wisdom, and stretched out the heavens by His *understanding?*" To maintain such a position would be to *distort* the Divine character, and to undermine all the conceptions we ought to form of the Deity, as wise, amiable, and adorable, and as "great in counsel and mighty in operation." If we beheld an artist exerting his whole energies, and spending his whole life in constructing a large complex machine which produced merely a successive revolution of wheels and pinions, without any useful end whatever in view, however much we might extol the ingenuity displayed in some parts of the machine, we could not help viewing him as a fool or a maniac in bestowing so much labor and expense to no purpose. For it is the *end* or design intended which leads us to infer the wisdom of the artist in the means employed. And shall we consider the ALL-WISE AND ADORABLE CREATOR OF THE UNIVERSE as acting in a similar manner? The thought would be impious, blasphemous, and absurd. It is only when we recognize the Almighty as displaying infinite wisdom in all his arrangements throughout creation, and boundless beneficence in diffusing happiness among countless ranks of intelligent existence, that we perceive him to be worthy of our admiration and gratitude, and of our highest praises and adorations. We are, therefore, irresistibly led to the conclusion, that the planets are the abodes of intelligent beings, since every requisite arrangement has been made for their enjoyment. This is a conclusion which is not merely probable, but absolutely certain; for the opposite opinion would rob the Deity of the most distinguishing attribute of his nature, by virtually denying him the perfection of infinite wisdom and intelligence.

SECTION IV.

ARGUMENT IV. The scenery of the heavens as viewed from the surfaces of the larger planets and their satellites, forms a presumptive proof that both the planets and their moons are inhabited by *intellectual* beings.

In the preceding chapter I have described at some length the celestial phenomena of the planets, both primary and secondary. From these descriptions it appears that the most glorious and magnificent scenes are displayed in the firmament of the remoter planets, and particularly in those of their satellites. Even the firmament of the moon is more striking and sublime than ours. But in the firmaments of some of the satellites of Jupiter and Saturn there are celestial scenes peculiarly grand and splendid, surpassing everything which the imagination can well represent, and these scenes diversified almost every hour. What should we think of a globe appearing in our nocturnal sky 1300 times larger than the apparent size of the moon, and every hour assuming a different aspect? of five or six bodies twenty or thirty times larger than our moon appears, all in rapid motion, and continually changing their phases and their apparent magnitudes? What should we think of a globe filling the twentieth part of the sky, and surrounded with immense rings, in rapid motion, diffusing a radiance over the whole heavens? When Jupiter rises to his satellites, and especially when Saturn and his rings rise to his nearest moons, a whole quarter of the heavens will appear in one blaze of light. At other times, when the sun is eclipsed, or when the dark sides of these globes are turned to the spectator, the *starry* firmament will open a new scene of wonders, and planets and comets be occasionally beheld in their courses through the distant regions of space.

The sublime and magnificent scenes displayed in those regions, the diversified objects presented to view; the incessant changes in their phases and aspects; the rapidity of their apparent motions; and the difficulty of determining the *real* motions and relative positions of the bodies in the firmament, and the true system of the world, lead us to the conclusion that the globes to which we allude are replenished, not merely with sensitive, but with *intellectual* beings. For such sublime and interesting scenes cannot affect inanimate matter, nor even mere sentient beings such as exist in our world; and we cannot suppose that the Creator would form such magnificent arrangements to be beheld and studied by *no rational beings* capable of appreciating their grandeur and feeling delight in their contemplation. If creation was intended as a display of the perfections and grandeur of the Divine Being, there must exist intelligent minds to whom such a display is exhibited; otherwise the material universe cannot answer this end, and might, so far as such a design is concerned, have remained forever shut up in the recesses of the Eternal Mind. Such scenes could not have been intended merely for the instruction or gratification of the inhabitants of the earth. For no one of its population has yet beheld them from that point of view in which their grandeur is displayed, and not one out of a hundred thousand yet knows that such objects exist. We are, therefore, irresistibly led to the conclusion that intelligent minds exist in the regions of Jupiter, Saturn, and Uranus, for whose pleasure and gratification these sublime scenes were created and arranged. Those minds, too, in all probability, are endowed with faculties superior in intellectual energy and acumen to those of the inhabitants of our globe. For the rapidity and complexity of the motions presented in the firmament of some of the satellites of Jupiter and Saturn, the variety of objects exhibited to view, and the frequent and rapid changes of their phases and apparent magnitudes, are such as to require the exertion of intellectual faculties more powerful and energetic than ours in order to determine the real motions and positions of the globes around them, and to ascertain the order of the planetary system of which they form a part. And it is likewise probable that their organs of vision are more acute and penetrating than those of men; otherwise they will never be able to discover either the earth, Mars, Mercury, or Venus, and, consequently, may suppose that such bodies have no existence.

SECTION V.

Argument V. The doctrine of a plurality of worlds may be argued from the consideration that, in the world we inhabit, *every part of nature is destined to the support of animated beings.*

There is, doubtless, a certain degree of pleasure in contemplating the material world, and surveying the various forms into which matter has been wrought and arranged, particularly in the admirable structure and movements of systems of bodies such as those which compose the planetary system. But there is something still more interesting and wonderful presented to the mind when we contemplate the worlds of life. The material world is only, as it were, the shell of the universe, the mere *substratum* of thought and sensation; living beings are its inhabitants, for whose sake alone matter is valuable, and for whose enjoyment it appears to have been created. In the organization of animated existences, in the various parts of which they are composed, in the adaptation of one part or organ to another, in their different functions, and the multifarious movements of which they are susceptible, without taking into consideration the soul that animates them, there is a display of the most admirable mechanism and the nicest contrivance, which is not to be found in earth or stones, in rocks of diamonds, or even in the figure of a planet and its motion round the sun.

Hence we find that the world in which we live teems with animated existence. Man is the principal inhabitant, for whose use and accommodation, chiefly, the terraqueous globe was formed and arranged. Had not the Creator intended to place upon its surface beings endowed with rational faculties, capable of enjoying happiness and recognizing the perfections of its author, it is not probable that it would have been created.—"God made man in his own image," "and gave him dominion over the fish of the sea, over the fowls of the air, and over every living thing that moveth upon the earth." After the light was formed, the bed of the ocean prepared, and the waters separated from the dry land; after luminaries were placed in the firmament, and plants and animals of all kinds brought into existence, the world appeared so magnificently adorned that it might have been thought perfect and complete. But all nature was yet destitute of sentiment and gratitude; there were no beings capable of recognizing the Power that formed them, or of praising the Author of their varied enjoyments. The world was still in a state of imperfection, until an intelligence was formed capable of appreciating the perfections of the Creator, of contemplating his works, and of offering to him a tribute of grateful adoration. Therefore "God created man in his own image," as the masterpiece of creation, the visible representative of his Maker, and the subordinate ruler of this lower world.

But although this globe was created chiefly for the residence of man, it was not destined *solely* for his enjoyment. It is impossible for him to occupy the *whole* of its surface, or of the appendages with which it is connected. There are extensive marshes, impenetrable forests, deep caverns, and the more elevated parts of lofty mountains, where human feet have never trod. There is a vast body of water which covers more than two-thirds of the surface of the globe, and the greater part of the atmosphere which surrounds the earth, which men cannot occupy as permanent abodes. Yet these regions of our world are not left destitute of inhabitants. Numerous tribes of animals range through the uncultivated deserts, and find ample accommodation suited to their nature, in rocks and mountains, in dens and caves of the earth.—The regions of the air are filled with winged creatures of every kind, from the ostrich and the eagle to the numerous tribes of flying insects almost invisible to the unassisted eye. The ocean teems with myriads of inhabitants which no man can number, of every form and size, from the mighty whale to the numerous tribes of *Medusæ*, of which several thousands of *billions* are contained in a cubical mile of water. Every sea, lake, and river is peopled with inhabitants; every mountain and marsh, every wilderness and wood, is plentifully stocked with birds and beasts, and numerous species of insects, all of which find ample accommodation, and everything necessary for their comfort and subsistence. In short, every part of matter appears to be peopled; almost every green leaf and every particle of dust has its peculiar inhabitants. Not only are the larger parts of nature occupied with living beings, but even the most minute portions of matter teem with animated existence. Every plant and shrub, and almost every drop of water, contains its respective inhabitants. Their number, in some instances, is so great, and their minuteness so astonishing, that thousands of them are connected within a space not larger than a grain of sand. In some small pools covered with a greenish scum, of only a few yards in extent, there are more living creatures than there are human beings on the surface of the whole earth.

Multitudes of animated beings are found in situations and circumstances where we should never have expected to perceive the principle of life. The juices of animals and plants, corrupted matter, excrements, smoke, dry wood, the bark and roots of trees, the bodies of other animals, and even their entrails, the dung-hill, and the dirty puddle, the itch, and other disorders which are attended with blotches and pimples, and even the hardest stones and rocks, serve to lodge, and in some measure to feed numerous tribes of living beings. The *number* of such creatures exceeds all human calculation and conception. There may be reckoned far more than a hundred thousand species of animated beings, many of these species containing individuals to the amount of several hundreds of times the number of the human inhabitants of our globe. It is supposed by some that the tremulous motion observed in the air during summer may be produced by millions of insects swarming in the atmosphere; and it has been found that the light which is seen on the surface of the ocean during the nights of summer is owing to an innumerable multitude of small luminous worms or insects sporting in the waters. All the numberless species of animals which exist on the different departments of our globe are likewise infinitely diversified in their forms, organs, senses, members, faculties, movements, and gradations of excellence. As Mr. Addison has observed, "the whole chasm of nature, from a plant to a man, is filled up with divers kinds of creatures rising one above another by such a gentle and easy ascent, that the little transitions and deviations from one species to another are almost insensible. This intermediate space is so well husbanded and managed, that there is scarce a degree of perception which does not appear in some one part of the world of life." Here we have an evidence both of the infinite wisdom and intelligence of the Divine Being, and of his boundless goodness in conferring existence and happiness on such a countless multitude of percipient beings.

Since, then, it appears that every portion of matter in our world was intended for the support and accommodation of animated beings, it would be absurd in the highest degree, and inconsistent with the character of the Deity and his general plan of operation, to suppose that the vast regions of the planets, so exceedingly more expansive than our globe, are left destitute of inhabitants.—Shall one small planet be thus crowded with a population of percipient beings of all descriptions, and shall regions four hundred times more expansive be left without one living inhabitant? Can the Deity delight to communicate enjoyment in so many thousands of varied forms to unnumbered myriads of sensitive existences in our terrestrial sphere, and leave the noblest planets of the system without a single trace of his benevolence? Can we suppose, for a moment, that while his *wisdom* shines so conspicuous in the mechanism of the various tribes of animals around us, no similar marks of intelligence are to be found in other regions of the universe? Such conclusions can never be admitted, unless we suppose that infinite wisdom and goodness have been *exhausted* in the arrangements which have been made in relation to our world, or that the Great Source of felicity is indifferent about the communication of happiness.

As far as our observation extends, it appears that the material world is useless, except in the relation it bears to animated and intellectual beings. *Matter* was evidently framed for the purpose of *mind;* and if we could suppose that the vast masses of matter in the heavens had no relation to mind, they must, then, have been created in vain; a supposition which would derogate from the moral character and the perfections of Him who is "the only wise God." A superior nature cannot be supposed to be formed for the sake of an inferior. A skillful artist would never think of designing that which is of the greatest dignity, or which requires the utmost precision and the nicest mechanism, for the sake of the inferior part of his workmanship. He does not construct the wheels and pinions of an orrery for the sake of the handle by which they are moved, or of the pedestal on which the instrument stands; nor does he contrive a timepiece merely for the sake of the shell or case in which it is to be inclosed. In like manner, we cannot imagine that *man* was made for the sake of the brutes, or the inferior animals for the sake of vegetables, or the yearly production of vegetables for the relief and comfort of the soil on which they grow. This would be to invert the order of the universe, and to involve us in the most palpable absurdity. The order of things always *rises upward*, by gentle and regular degrees, from inanimate matter, through all the gradations of vegetable, animal, and immaterial existence, until we arrive at the Eternal and Incomprehensible Divinity. Hence it appears that the earth must have been formed, not for itself, but for the sake of the vegetable, sensitive, and intellectual beings it supports; and, by a parity of reasoning, the planets, most of which are much more spacious and more magnificently adorned, must have been formed and arranged for the sake of superior natures.

"Existence," as a certain writer has observed, "is a blessing to those beings only which are indued with perception, and is, in a manner, thrown away upon dead matter, any further than as it is subservient to beings which are conscious of their existence." Accordingly we find, from the bodies which lie under our observation, that matter is only made as the basis and support of living beings, and that there is little more of the one than what is necessary for the existence and the ample accommodation of the other. The earth, as to amplitude of space, would contain a hundred times the number of animated beings it actually supports; and the ocean might perhaps contain thousands more than what are found amid its recesses; but, in such a case, they would not have free scope for their movements, nor experience all the comforts and accommodations they now enjoy.

From what has been stated, it appears that the Divine Goodness is of so communicative a nature that it seems to *delight* in conferring existence and happiness on every order of perceptive beings, and therefore, has left no part connected with the world in which we live without its inhabitants; and that no creature capable of feeling the pleasure of existence might be omitted in the plan of benevolence, there is an almost infinite *diversity* in the rank and order of percipient existence.—The scale of sensitive being begins with those creatures which are raised just above dead matter. Commencing at the polypus and certain species of shell-fish, it ascends by numerous gradations until it arrives at man. How far it may ascend beyond this point is beyond the limits of our knowledge to determine. Had only one species of animals been created, none of the rest would have enjoyed the pleasures of existence. But in the existing state of things, all nature is full of enjoyment, and that enjoyment endlessly diversified, according to the rank and the percipient powers of the different species of animated existence. It would, therefore, be a reflection on the *goodness* as well as on the wisdom of the Divine Being, were we to suppose that no traces of Divine beneficence were to be found amid the expansive regions of the planetary globes. It would form a perfect *contrast* to the operations of Infinite Benevolence, as displayed in our terrestrial system, and would almost lead us to conclude that the same Almighty Agent did not preside in both these departments of the universe. But we may rest assured that the Deity always acts in harmony with his character throughout every part of his dominions; and, therefore, we may confidently conclude that countless multitudes of sensitive and intellectual beings, far more numerous and diversified than on earth, people the planetary regions.

From what has been stated on this subject, we may likewise conclude with certainty that the planetary worlds are not peopled merely with animal existences, but also *with rational and intellectual natures*. For the scenes displayed in most of the planets cannot be appreciated by mere sensitive beings, nor are they calculated to afford them any gratification. Beside, if it be one great design of the Creator to manifest the glory of his perfections to other beings, none but those who are furnished with rational faculties are capable of recognizing his attributes as displayed in his works, and of offering to him a tribute of thanksgiving and adoration. Such intelligences, we have every reason to believe, may far surpass the human race in their intellectual powers and capacities. There is an infinite gap between man and the Deity, and we have no reason to believe that it is entirely unoccupied. There is a regular gradation from inanimate matter and vegetative life through all the varieties of animal existence until we arrive at man. But we have no reason to believe that the ascending scale terminates at the point of the human faculties, unless we suppose that the soul of man is the most perfect intelligence next to the Divinity. If the scale of being rises by such a regular process to man, by a parity of reasoning we may suppose that it still proceeds gradually through those beings that are endowed with superior faculties; since there is an immensely greater space between man and the Deity than between man and the lowest order of sensitive existence. And although we were to conceive the scale of *intellectual* existence above man rising thousands of times higher than that which intervenes between inanimate matter and the human soul, still there would be an infinite distance between the highest created intelligence and the Eternal Mind which could never be overpassed. It is quite accordant with all that we know of the perfections and operations of the Deity to conclude that such a progression of intellectual beings exists throughout the universe; and, therefore, we have reason to believe that in some of the planets of our system there are intellectual natures far superior, in point of mental vigor and capacity, to the brightest geniuses that have ever appeared upon earth; and in other systems of creation the scale of spiritual progression may be indefinitely extended far beyond the limits to which human imagination can penetrate. In the contemplation of such scenes of percipient and intelligent existence, we perceive no boundaries to the prospect; the mind is overwhelmed amid the immensity of being, and feels itself unable to grasp the plans of Eternal Wisdom, and the innumerable gradations of intelligence over which the moral government of the Deity extends; and, therefore, we may justly conclude wonders of power, wisdom, and benevolence still remain for the admiration of intellectual beings, which the scenes of eternity alone can disclose.

Intellectual beings may likewise be distinguished into those which are linked to *mortal*, and those which are connected with *immortal* bodies. In the present state of our terrestrial system immortal bodies cannot exist. Had immortality been intended for man on earth, Infinite Wisdom would have adopted another plan; for the constitution of the earth, the atmosphere, and the waters, is not adapted to the support and preservation of immortal beings; that is, of those intelligences which inhabit a system of corporeal organization. From the reciprocal action of solids and fluids, of earth, air, and water, *life* results; and this very action continued, according to the laws which now operate, is the natural cause of *death*, or the dissolution of the corporeal system. But in other worlds a system of means may be adapted for preserving in perpetual activity, and to an indefinite duration, the functions of the corporeal machine which is animated by the intellectual principle; as would probably have happened in the case of man, had he retained his original moral purity and his allegiance to his Maker. Intelligent beings may likewise exist which are destined to pass from one state of corporeal organization to another, in a long series of changes, advancing from one degree of corporeal perfection to another, until their organical vehicles become as pure and refined as light, and susceptible of the same degree of rapid motion. The butterfly is first an egg, then a worm, afterward it becomes a chrysalis, and it is not before it has burst its confinement, that it wings its flight, in gaudy colors, through the air Man is destined to burst his mortal coil, to enter a new vehicle, and at last to receive a body "incorruptible, powerful, glorious, and immortal."—Varieties analogous to these may exist throughout other regions of the universe. If there are not in nature two leaves precisely alike, or two trees, two cabbages, two caterpillars, or two men and women exactly similar in every point of view in which they may be contemplated, how can we suppose that there can be two planets or two systems of planets exactly alike, or that the corporeal organs and faculties of their inhabitants in every respect resemble each other? Every globe and every system of worlds has doubtless its peculiar economy, laws, productions, and inhabitants. This conclusion is warranted from all that we know of the operations of the Creator; it exhibits, in a striking point of view, the depths of his wisdom and intelligence, and it opens to immortal beings a prospect boundless as immensity, in the contemplation of which their faculties may be forever exercised, and their views of the wonders of Creating Power and wisdom continually extending, while myriads of ages roll away.

In the preceding pages I have endeavored to illustrate the doctrine of a plurality of worlds, from the considerations that there are bodies in the planetary system of such *magnitudes* as to afford ample scope for myriads of inhabitants; that there is a *general similarity* among all the bodies of the system, which affords a presumptive evidence that they are intended to subserve the same ultimate designs; that, connected with the planets, there are *special arrangements* which indicate their *adaptation* to the enjoyment of sensitive and intellectual beings; that the *scenery of the heavens, as viewed from the surfaces of the larger planets and their satellites*, forms a presumptive proof of the same position; and that the fact that *every part of nature in our world is destined to the support of animated beings*, affords a powerful argument in support of this doctrine. These arguments, when viewed in all their bearings, and in connection with the wisdom and benevolence of the Divine Being, may be considered as amounting to moral demonstrations that the planets and their satellites, as well as other departments of the universe, are the abodes of sensitive and intelligent natures. These, however, are not all the considerations or arguments which might be brought forward in proof of this position. Many others, founded on a consideration of the nature and relations of things, and the attributes of the Divinity, and particularly some powerful arguments derived from the records of Revelation, might have been stated and particularly illustrated. But I shall leave the further consideration of this topic to another volume, in which we shall take a survey of the scenery of the starry firmament, and of other objects connected with the science of the heavens.

On the whole, the doctrine of a plurality of worlds is a subject of considerable importance, and in which every rational being, who is convinced of his immortal destination, is deeply interested. It opens to our view a boundless prospect of knowledge and felicity beyond the limits of the present world, and displays the ineffable grandeur of the Divinity, the magnificence of his empire, and the harmonious operation of his infinite perfections. Without taking this doctrine into account, we can form no *consistent* views of the character of Omnipotence and of the arrangements which exist in the universe. Both his wisdom and his goodness might be called in question, and an idea of the Supreme Ruler presented altogether different from what is exhibited by the inspired writers in the records of Revelation.—When, therefore, we lift our eyes to the heavens, and contemplate the mighty globes which roll around us; when we consider that their motions are governed by the same common laws, and that they are so constructed as to furnish accommodation for myriads of perceptive existence, we ought always to view them as the abodes of intelligence and the theaters of Divine Wisdom on which the Creator displays his boundless beneficence; for "his tender mercies," or the emanations of his goodness, "are diffused *over all his works.*" Such views alone can solve a thousand doubts which may arise in our minds, and free us from a thousand absurdities which we must otherwise entertain respecting the Great Sovereign of the universe. Without adopting such views, the science of the heavens becomes a comparatively barren and uninteresting study, and the splendor of the nocturnal sky conveys no ideas of true sublimity and grandeur, nor is it calculated to inspire the soul with sentiments of love and adoration. In short, there appears to be no medium between remaining in ignorance of all the wonders of Power and Wisdom which appear in the heavens, and acquiescing in the general views we have attempted to illustrate respecting the economy of the planets, and their destination as the abodes of reason and intelligence. But, when such views are recognized, the bodies in the heavens become the noblest objects of human contemplation, the Deity appears invested with a character truly amiable and sublime, and a prospect is opened to immortal beings of a perpetual increase of knowledge and felicity, throughout all the revolutions of an interminable existence.

APPENDIX.

PHENOMENA OF THE PLANETS FOR THE YEARS 1838, 1839.

For the sake of those readers who may feel a desire occasionally to contemplate the heavens and to trace the motions of the planetary orbs, the following sketches are given of the positions and motions of the planets for two years posterior to 1837.

POSITIONS, ETC., OF THE PLANETS FOR 1838.

1. *The Planet Mercury.*

This planet can be seen distinctly by the naked eye only about the time of its greatest elongation; and to those who reside in northern latitudes it will scarcely be visible, even at such periods, if it be near the utmost point of its southern declination.

The following are the periods of its greatest elongation for 1838: January the 3d it is at its *eastern* elongation, when it is 19¼ degrees *east* from the sun, and will be seen in the *evening* about thirty or forty minutes after sunset, near the south-west, at a little distance from the point where the sun went down. But as it is then in 20° 41′ of south declination, its position is not the most favorable for observation. Its next greatest elongation is on February 12, when it is 26° 10′ to the *west* of the sun, and will be seen in the *morning*, before sunrise, near the south-eastern quarter of the horizon. April 25 it will again be seen in the *evening* at the eastern elongation, 20° 20′ east of the sun, when it is in 21° 43′ of north declination. It will be seen at this time about 15 degrees north of the western point of the horizon, almost immediately above the place where the sun went down. During five days before and after the time now specified there will be favorable opportunities for detecting Mercury with the naked eye or with a small opera-glass. On June 12 is its greatest *western* elongation, at which time it is 23° 5′ west of the sun, and is to be looked for in the *morning*, before sunrise, near the north-eastern part of the horizon; but the strong twilight at this season will probably prevent it from being distinguished by the naked eye. Its next greatest *eastern* elongation is on August 23, when it is 27¼ degrees from the sun. It will be seen, for nearly an hour after sunset, a little to the south of the *western* point of the compass, and a few degrees above the horizon. It may be seen during ten or twelve days before the period here stated, and six or eight days after it. This will form one of the most favorable periods which occur throughout this year for observing Mercury. October 4 it will again be at its greatest *western* elongation, when it will be seen in the *morning* in a direction nearly due east. December 17 it is at its greatest *eastern* elongation, but its southern declination being then more than 24 degrees, it will set in the S. W. by S. point of the compass a few minutes after the sun, and will consequently be invisible to the naked eye.

The periods most favorable for detecting this planet in the *evenings* are April 25 and August 23; and in the *mornings*, February 12 and October 4. During the interval of a week or ten days, both before and after the time of greatest elongation, the planet may generally be seen in a clear sky, when in such favorable positions as those now stated.

2. *The Planet Venus.*

This planet will appear as an evening star during the months of January and February. About the beginning of January it will be seen near the south-west quarter of the heavens a few minutes after sunset. About the beginning of February it will set nearly due west. It will be visible in the evening until about the 25th of February, after which its nearness to the sun will prevent it from being distinguished. Throughout the whole of its course during these two months it will appear of the figure of a crescent when viewed with a telescope, and the crescent will appear most slender about the end of February (see Fig. 12, p. 31). On March 5 it passes its *inferior* conjunction with the sun, after which it will be no longer seen in the evenings for the space of ten months. It then becomes a morning star; and, about eight days after its conjunction, will be seen in the *morning*, before sunrise, a little to the south of the eastern point of the horizon. From this period until near the middle of May it will appear of a crescent form. Its greatest brilliancy will be on April 10; its greatest elongation from the sun on May 14, when it will appear of nearly the form of a half moon, and its *superior* conjunction on December 18, soon after which it will again be seen as an evening star.

The brilliancy of this planet is such that it can scarcely be mistaken by any observer, especially when its position in the heavens is pointed out.

3. *The Planet Mars.*

This planet will not be much noticed by common observers until near the end of the year.—About the beginning of March it is in conjunction with the sun, when it is farthest from the earth, about a month or two before and after which period it is scarcely distinguishable from a small star. From April to December it will be visible only in the *morning*, in an easterly direction; but its apparent size will gradually increase until the end of the year. It is distinguished from the fixed stars and from the other planets by its ruddy appearance.

4. *The Planets Vesta, Juno, Ceres, and Pallas.*

These planets are not perceptible by the naked eye. The best time for observing them with telescopes is when they are at or near the period of their opposition to the sun, when they are nearest to the earth, and even then it will be difficult to detect them without the assistance of transit or equatorial instruments.

Vesta will be in opposition to the sun on the 29th December, its right ascension being 6h. 31′ 47″, and its declination 22° 4½′ north. At midnight it will be due south, at an elevation of 60 degrees above the horizon, in the latitude of 52 degrees north, about 15 degrees to the south-west of the star Pollux, and 7½ degrees north of *Gamma* Gemini.

Juno is in opposition on the 17th June, in right ascension 17h. 46½′, and south declination 4½°. It will be on the meridian at midnight, at an elevation of 33½ degrees above the southern horizon.

Neither *Ceres* nor *Pallas* will be in opposition to the sun during this year.

5. *The Planet Jupiter.*

This planet will make a very conspicuous appearance in the heavens during the winter and spring months. About the beginning of January it will rise, a little to the north of the eastern point of the horizon, a few minutes after ten o'clock in the evening, and will pass the meridian, at an elevation of 43½ degrees, about half past four in the morning. About the middle of February it will rise about seven in the evening, nearly in the same direction, and will come to the meridian about half past one in the morning.—During the months of January and February it will be seen either in the evenings or the mornings. About the middle of January it will be seen, in a south-westerly direction, about six o'clock in the morning. From the beginning of March until the end of August it will be seen in the evenings without interruption when the sky is clear. On the 22d September it is in conjunction with the sun, but it will seldom be noticed for a month before this period. During the months of November and December it will be again seen in the east, only in the morning, some time before the rising of the sun.

This planet can scarcely be mistaken, as it is next to Venus in apparent magnitude and splendor. It will appear most brilliant about the beginning of March, when it is in opposition to the sun, and its satellites and belts will present an interesting sight when viewed with a good telescope. At present (November 22, 1837), four belts, nearly equidistant from each other, are distinctly visible with a power of 200 times. Their appearance is very nearly similar to what is represented in Fig. 56, p. 64, so that a considerable change has taken place in their appearance since last June, when they appeared nearly as in Fig. 52, p. 61. At that time the middle belt was the only one easily perceptible, while the other two, at the north and south extremities, appeared extremely faint and obscure. At present all the four belts are distinctly marked.

6. *The Planet Saturn.*

This planet passed its conjunction with the sun on the 12th November, 1837. From the beginning of the year until about the middle of April it will be visible chiefly in the mornings. On the first of January it will rise near the south-east, about twenty minutes past four in the morning, and will pass the meridian about forty-eight minutes past eight, at an elevation of 21 degrees above the southern horizon. On the first of April it will rise at half past ten in the evening, and about midnight will be seen near the south-east about ten or twelve degrees above the horizon. From this period Saturn will be visible in the evenings until near the end of October, rising every evening at an earlier hour than on the preceding. On the 16th May it is in opposition to the sun, when it will rise near the south-east at half past seven, and come to the meridian at midnight. During the months of August, September, and October, it will be seen chiefly in the *south-west* quarter of the heavens after sunset, at a small elevation above the horizon. It will be very perceptible during September and October, on account of its low altitude at sunset. It will be in conjunction with the sun on the 24th November.

This planet is not distinguished for its brilliancy to the naked eye, though it exhibits a beautiful appearance through the telescope. It is of a dull leaden color, and is not easily distinguished from a fixed star except by the steadiness of its light, never presenting a twinkling appearance as the stars do, and from which circumstance it may be distinguished from neighboring stars. The best times for telescopic observations on this planet will be in the months of April and May, when its ring will appear nearly as represented in Fig. 63, p. 71.

7. *The Planet Uranus.*

This planet is, for the most part invisible to the naked eye. The best time for detecting it by means of a telescope, is when it is at or near the period of its opposition to the sun, which happens on the 3d September. At that time it passes the meridian at midnight, at an elevation of about 30⅓ degrees above the horizon. It is situated nearly in a straight line between the star *Fomalhaut* on the south and *Markab* on the north, being nearly in the middle of the line, about 22½ degrees distant from each. It is in the neighborhood of several telescopic stars. On account of its slow motion, its position in respect to the above stars will not be much altered for a month or two. On the 1st of November it passes the meridian at eight o'clock in the evening. Its *right ascension*, or distance from the first point of Aries, is then 22h. 42′ and its declination 9° 4′ south.

N. B.—In the above statements the observer is supposed to be in fifty-two degrees north latitude. In places a few degrees to the north or south of this latitude, a certain allowance must be made for the times of rising, and the altitudes which are here specified. To those who reside in lower latitudes than fifty-two degrees, the altitudes of the different bodies will be *higher*, and to those in higher latitudes the altitudes above the horizon will be *lower* than what is here stated.

PHENOMENA OF THE PLANETS FOR 1839.

1. *Mercury.*

The greatest *western elongation* of this planet happens on the 26th of January, when it is 24° 50′ west of the sun. It will be seen near the south-east a little before seven in the morning. On the seventh of April, and a few days before and after it, it will be seen in the evening in a direction west by north. On the 24th of May it will be seen in the morning, in a direction a little to the north of the eastern point, before sunrise. Its next elongation will happen on the fifth of August, when it is twenty-seven and one-third degrees distant from the sun. At this period, and a fortnight before and a little after, it will be seen near the west point, or a little north of it, about nine o'clock in the evening or a few minutes before it. This will be a favorable opportunity for distinguishing this planet with the naked eye. It will be again seen in the morning, about five o'clock, a little to the north of the east point, on September 18. Its next greatest elongation will be on the 30th of November, when it will appear in a direction south-west-by-south about the time of sunset. This will be a very unfavorable position for attempting to distinguish Mercury. It passes its inferior conjunction with the sun on the 18th December.

2. *Venus.*

This planet will be an evening star from the beginning of the year until 6th October, when it passes its inferior conjunction with the sun. It will not, however, be much noticed until about the beginning of March, on account of its nearness to the sun and its southern declination. It will appear most brilliant during the months of May, June, July, August, and beginning of September, when it will be seen at a considerable elevation in the western and north-western quarter of the heavens a few minutes after sunset. About the middle of October, or a few days before, it will appear as a *morning* star near the *south-eastern* quarter of the sky, and will continue as a morning star until near the end of the year.

3. *Mars.*

During the months of February, March, and April, this planet will appear in its greatest luster. It will be in opposition to the sun on the 12th March, at which period it is nearest to the earth, and will appear twenty-five times larger in surface than in the opposite part of its orbit. At this period it will rise about half past five in the evening, a little to the north of the *east* point, and will come to the meridian at midnight, at an altitude of forty-five degrees. It will be easily distinguished from the neighboring stars by its size and its ruddy appearance. At this time the planet Jupiter will appear in a direction about twenty-two degrees south-east of Mars. From the month of May until the end of the year Mars will be visible in the evenings, but its apparent size will be gradually diminishing, and, on account of its southern declination, will not be much noticed after the month of September. On the 19th July, at forty-six minutes past nine o'clock in the evening, Mars and Jupiter will be in conjunction, at which time Mars will be one degree and a half to the south of Jupiter. They will then be seen near the western point, at a small elevation above the horizon.

4. *Vesta, Juno, Ceres, and Pallas.*

Juno arrives at its opposition to the sun on the 12th October, at 1h. 32′, P. M. It passes the meridian at midnight, or at 12h. 2½′, at an altitude of

34° 21′, and is then about twelve degrees west of the star *Mira*. Declination 3° 39′ south, and right ascension, 1h. 26′.

Pallas is in opposition to the sun April 1, at 7h. 10′, A. M. Right ascension 13h. 12′ 42″. Declination 14° 21′ *north*. It passes the meridian at midnight, at an elevation of 52° 22′. It will then be about fourteen degrees south-west from the bright star *Arcturus*.

Ceres is in opposition April 6, at 7h. 8′, P. M. Right ascension 13h. 23′ 40″. Declination 7° 54′ *north*. It passes the meridian at midnight, at an altitude of nearly forty-six degrees. It will then be seen, by means of a telescope, at about twelve degrees south-west from *Arcturus*.

The planet Vesta is not in opposition to the sun this year.

5. *Jupiter.*

During the months of January and February this planet will be chiefly seen in the morning. On the 12th January it rises about midnight, a little to the south of the eastern point of the horizon, and comes to the meridian at forty minutes past five in the morning, at an altitude of about thirty-two degrees. On the 12th March it rises at eight in the evening, and will be seen near the south-east part of the heavens about eleven and twelve o'clock, P. M. On the 3d April, it is in opposition to the sun, when it rises about half past six, P. M., and comes to the meridian about midnight. From this period it will form a conspicuous object in the evening sky until near the end of September. It arrives at its conjunction with the sun on the 22d October, after which it will be seen only in the morning throughout the month of December and the latter part of November. On the 20th March, at one o'clock in the morning, all the satellites of Jupiter will appear on the east, or right-hand side of the planet, *in the order of their distances* from Jupiter. The same phenomenon will happen on August 1, at forty-five minutes past eight, and 20th September, at 7h., P. M.

6. *Saturn.*

This planet will be visible only in the morning during the months of January, February and March, and will then be seen toward the southern and south-eastern parts of the sky. On the first of February it will rise, about half past two in the morning, near the south-east, and will come to the meridian at forty-nine minutes past seven, at an elevation of eighteen degrees above the horizon. On the first of April it will rise at forty-two minutes past eleven in the evening, and will pass the meridian a few minutes before four in the morning. It will be in opposition to the sun on the 29th May, when it will rise in the south-east at forty-five minutes past seven, P. M., and will pass the meridian at midnight, at an altitude of eighteen and a half degrees above the southern point of the horizon. This will be a favorable opportunity for viewing its ring with good telescopes, when it will appear nearly in its full extent, as represented Fig. 65, p. 71. From this period Saturn will generally be visible in the evening until about the end of October, when its low altitude and its proximity to the sun will prevent its being distinguished by the naked eye. About the middle of August, at nine o'clock in the evening, it will be seen near the south-west at a small elevation above the horizon. It will be in conjunction with the sun on the fifth December, after which it will be invisible to the naked eye until the beginning of 1840.

7. *Uranus.*

This planet will be in opposition to the sun on the 7th of September, at 30 minutes past seven in the evening. Right ascension 23h. 4′, or 346° east from the point Aries, reckoned on the equator. South declination 6° 52½′. It will come to the meridian at midnight at an elevation of 31° 8′ above the horizon. At this time it is in the immediate vicinity of the star *Phi*, Aquarii. On the 25th of August, at 20 minutes past one in the morning, it is in conjunction with this star, being only 15′ or one-quarter of a degree to the north of it, at which time the planet and the star, if viewed with a telescope of moderate power, will both appear in the field of view. The months of August, September, October, and November will be the most eligible periods for detecting this planet with the telescope. On the 1st of November it passes the meridian at 15 minutes past eight in the evening, at an altitude of 30½ degrees.

N. B.—The preceding descriptions of planetary phenomena are chiefly intended to inform common observers as to the seasons of the year when the different planets may be seen, and the quarters of the heavens to which they are to direct their attention in order to distinguish them.

It may not be improper to observe, that the planets in general cannot be distinguished by the naked eye for about a month before and after their conjunctions with the sun, except *Venus*, which may frequently be seen within a week before and after its *inferior* conjunction. But this planet will sometimes be invisible to the naked eye for a month or two after its *superior* conjunction with the sun.

Should the above descriptions of celestial phenomena prove acceptable to general readers, they may be continued in future years.

THE

SIDEREAL HEAVENS

AND

OTHER SUBJECTS CONNECTED WITH

ASTRONOMY,

AS ILLUSTRATIVE OF THE CHARACTER OF THE DEITY, AND OF AN INFINITY OF WORLDS.

"The worlds were framed by the word of God."—PAUL.

PREFACE.

THE favorable reception which the volume entitled "CELESTIAL SCENERY," has met with from the public, both in Britain and America, has induced the Author to extend his survey to other sublime scenes connected with the science of Astronomy. The chief object of the work alluded to, was to illustrate, more fully than had previously been attempted, the scenes connected with the planetary system. In the present volume, the Author has directed the attention of his readers to scenery of a still more elevated and sublime description, connected with the "Sidereal Heavens." All the facts related to this subject, which can be considered as interesting to general readers, have been particularly detailed, and in such a manner as to be generally comprehensible by those who have little knowledge of mathematical science, or the more abstruse parts of astronomy.

In describing such sublime scenes as are here unfolded, the Author, as on former occasions, has freely indulged in such remarks and moral reflections as were naturally suggested by the grandeur of his subject; and has endeavored to lead the minds of his readers to the contemplation of the attributes and the agency of that Almighty Being, by whom the vast system of universal nature was at first brought into existence, and by whose superintending care it is incessantly conducted in all its movements.

The subject of a plurality of worlds has been resumed, and additional arguments, both from reason and revelation, have been brought forward so as to exhibit this position, not merely as conjectural or highly probable, but as susceptible of moral demonstration. For the gratification of amateur observers possessed of telescopes, particular descriptions have been given of the *positions* or some of the more remarkable phenomena in the sidereal heavens, that they may be induced to contemplate them with their own eyes. For a similar reason, the Author has described the various aspects of the heavens throughout the year, and the position of the planets for 1840 and 1841. As the subject of *comets* was unavoidably omitted in the preceding volume, the Author has condensed, in the concluding chapter, the greater part of the facts which have been ascertained respecting the nature, phenomena, and influence of those anomalous bodies.

It was originally intended, had the limits of the present volume permitted, to direct the attention of the student to other subjects related to the scenery of the heavens, and to the construction and application of some of those instruments which are devoted to celestial observations. Should the work now published meet with a favorable reception, the Author intends—in a smaller volume than the present—to elucidate some of the subjects to which he alludes, especially the following:—the construction and use of optical instruments, particularly the reflecting and achromatic telescope, and the equatorial. As the Author has performed a great variety of experiments in relation to such instruments, he hopes to have it in his power to suggest some new and useful hints in reference to their construction and improvement. The doctrine of eclipses and occultations, the precession of the equinoxes, &c.—the construction of observatories, and the manner of using astronomical instruments,—the *desiderata* in astronomy, and the means by which the progress of the science may be promoted,—the practical utility, physical and moral, of astronomical studies,—their connection with religion, and the views they unfold of the attributes and the empire of the Creator, with several other correlative topics, will likewise be the subject of consideration. The whole to be illustrated with appropriate engravings, many of which will be original.

Broughty Ferry, near Dundee

CONTENTS.

INTRODUCTION.

Page

Imperfect knowledge of the Sidereal Heavens. Discoveries by the telescope. Herschel's observations. Sidereal science in its infancy. Boundless nature of the subject............ 9

CHAPTER I.

A GENERAL VIEW OF THE STARRY HEAVENS, WITH REPRESENTATIONS OF DETACHED PORTIONS OF THE FIRMAMENT.

Splendid and august appearance of the heavens. Sentiments and emotions they produce. Inquiries suggested by a contemplation of the wonders they unfold. Appearance of the stars and constellations about the middle of January. Delineations of certain stars and constellations at that time visible. Representations of certain portions of the heavens in the beginning of September. View and description of the circumpolar stars. General remarks in reference to these stars.. 11

CHAPTER II.

OF THE ARRANGEMENT OF THE STARS INTO CONSTELLATIONS, WITH SKETCHES OF THEIR MYTHOLOGICAL HISTORY.

Invention of the *Zodiac*. Mode in which it was divided by the ancients. Origin of the names by which its signs are distinguished. List of the constellations, with the number of stars in each. Arrangement of the stars into different magnitudes. Catalogues of the stars. Origin of the celestial hieroglyphics. Greek alphabet.. 18

CHAPTER III.

ON THE PROPRIETY OF ADOPTING A MORE NATURAL ARRANGEMENT AND DELINEATION OF THE STARRY GROUPS.

Introductory remarks. Reasons why the present nomenclature and arrangement of the stars should be changed. Principles on which a new arrangement should be formed. Improvements which might be adopted in the meantime in celestial globes and planispheres. Delineation of Orion. Sir J. Herschel's opinion. British Association.................. 23

CHAPTER IV.

ON THE DISTANCES OF THE STARS.

Measures of distance. Annual parallax. Mode of investigating it. Galileo, Hook, and Flamstead's methods. Molyneux's and Bradley's observations. Aberration. Supposed distance of the nearest star. Herschel's investigations. Professor Bessel's determination of the parallax of 61 Cygni. Amazing distance of this star. Reflections on the immense spaces of the universe. Scriptural representations of the Deity. Whether man may ever traverse distant regions.. 27

CHAPTER V.

ON THE MAGNITUDE OF THE STARS.

Difficulty of ascertaining the real and apparent magnitude of the stars Supposed magnitude of some stars. Certainty that their real magnitudes are very great. Popular illustration of the distances and magnitudes of the stars. 23

CHAPTER VI.

ON NEW STARS.

New star discovered by Hipparchus. Particular description of the new star which appeared in 1572—delineation of its position. Description of the new star of 1604, and of several others. Mysterious nature of these bodies. Opinions which have been formed respecting them. Futility of some of these opinions. Such bodies not annihilated. Probable cause of such phenomena. Concluding reflections. 36

CHAPTER VII.

ON VARIABLE STARS.

Descriptions of the periods and phenomena of some of these bodies, Stella Mira, Algol, *Eta* Antinoi, &c. Conjectures respecting their nature. Probable causes of the phenomena of variable stars, illustrated by figures. Stars which are lost. Stars which have changed their magnitudes. Stars which have recently become visible. New creations. Omnipotent energies. Scenes of grandeur in the heavens. 41

CHAPTER VIII.

ON DOUBLE STARS AND BINARY SYSTEMS.

Variety a characteristic of the works of the Deity. Double stars observed by Herschel and others—their number—their motions. Herschel's observations on the motion of the double star *Castor*. Period of revolution illustrated by a diagram. Periods of revolution of several double-stars. Occultation of one star by another. Orbits of double-stars—telescopic views of. Scenes exhibited by the revolutions of double stars. Distances of binary systems. Planets connected with them. Velocity of motions. Number of such systems. Contrasted colors of double stars. Effects produced on planets by colored suns. Representations of a binary system. Proposed method of determining the distances of double stars. General remarks on this method, &c. 44

CHAPTER IX.

ON TREBLE, QUADRUPLE, AND MULTIPLE STARS.

General remarks. Treble star in Cancer. Delineation of treble and quadruple systems. Quadruple star in Lyra. Oscillating suns. Problem of three bodies. Reflection on multiple systems. List and positions of treble and multiple stars. 54

CHAPTER X.

ON THE MILKY WAY.

Grandeur of the sidereal heavens. Position of the Milky Way, and the constellations through which it passes. Multitude of stars it contains. Sir W. Herschel's observations on this zone. Estimate of the *number* of stars it may contain. Number of visible stars in the heavens. *Distances* of some of the stars in this zone. Reflections on the scene exhibited by the Milky Way. Position of our sun in this zone. Delineations of the *form* of the Milky Way. Schroeter's observations. Herschel's remarks on its structure. Its appearance in the southern hemisphere. . . . . 5[illegible]

CHAPTER XI.

ON GROUPS AND CLUSTERS OF STARS.

The Pleiades—telescopic view of—(see *Appendix*). Hook and Mitchell's remarks on this cluster. *Coma Berenices*—*Præsepe*—telescopic view of. *Perseus*. Delineation of a group in Orion's sword. Such groups form interesting objects of contemplation—immensity of the universe. Views and descriptions of stars. Variety of firmaments.................................... 62

CHAPTER XII.

ON THE DIFFERENT ORDERS OF THE NEBULÆ.

SECTION I.

GENERAL REMARKS ON THE SUBJECT OF NEBULÆ.

Boundless extent of the universe. Sir W. Herschel's remarks on this subject. Lambert's views of the universe. Number of discovered nebulæ. Size, grandeur, and different forms of the nebulæ.. 66

SECTION II.

ON THE VARIOUS KINDS OF NEBULÆ.

Clusters of stars. *Resolvable* nebulæ. *Irresolvable* nebulæ. Views and descriptions of various kinds of nebulæ — globular — elliptical — annular — spheroidal. Nebulous stars. Diffused nebulosities. Nebulosities joined to nebulæ, &c.. 68

SECTION III.

ON PLANETARY NEBULÆ.

General description. Enormous magnitude of such bodies. Positions of some of these nebulæ. 73

SECTION IV.

ON NEBULÆ IN ORION.

Its position. Huygens' description of it. Delineations of this nebulæ. Herschel's descriptions and remarks. The author's observations. Its immense magnitude. Reflections and remarks.. 75

SECTION V.

ON THE NEBULAR HYPOTHESIS.

Inquiries and conjectures suggested by the nebulæ. Premature conclusions which have been deduced. Remarks and reflections in relation to the subject of nebulæ..................... 77

SECTION VI.

Catalogue of some of the larger nebulæ.. 78

CHAPTER XIII.

ON THE ABERRATION OF THE STARS, AND ON THEIR PROPER MOTIONS.

Bradley and Molyneux's observations. Aberration of light explained and illustrated. Sir J. Herschel's explanation. Other illustrations. Conclusions deduced from the aberration of the stars. Proper motions of the stars when first observed. Specimens of their annual motions. Velocity with which they move...... 81

CHAPTER XIV.

ON THE DESTINATION OF THE STARS; OR, THE DESIGNS THEY ARE INTENDED TO SUBSERVE IN THE SYSTEM OF THE UNIVERSE.

Utility of the stars to our globe. This not the chief design of their creation. Are suns to other worlds. Arguments which prove this position. Constitute the chief part of the universe. Direct indications of their being the centers of systems. Immense extent of the Divine empire.. 84

CHAPTER XV.

ON UNKNOWN CELESTIAL BODIES—ON METEORIC PHENOMENA—AND ON SHOOTING STARS.

Probable existence of large opaque globes throughout space. Central bodies. Lambert's views on this subject. Meteoric phenomena. November meteors. Various descriptions of their phenomena, illustrated by a figure. Seen in different parts of the world. Circumstances attending their fall. Their appearance in France. Dr. Olmsted's deductions respecting their origin, illustrated by a diagram. Arago's opinion. General reflections.................... 88

CHAPTER XVI.

ARGUMENTS ILLUSTRATIVE OF THE DOCTRINE OF A PLURALITY OF WORLDS.

This doctrine accordant with the *infinity*, the *eternity*, the *wisdom*, and the *benevolence* of the Divine Mind. Exhibits a magnificent idea of Deity. Power always accompanied with wisdom and goodness. Absurdities involved in the opposite opinion. Harmony of the Divine Perfections. Summary of arguments.................................... 94

CHAPTER XVII.

A PLURALITY OF WORLDS PROVED FROM DIVINE REVELATION

Introductory remarks. Psalm viii, 3, 4. Isaiah xl, 15, 17. Nehemiah ix, 6, &c. Such passages explained and illustrated.................................... 100

CHAPTER XVIII.

ON THE PHYSICAL AND MORAL STATE OF THE BEINGS THAT MAY INHABIT OTHER WORLDS.

They are *sentient* beings—endowed with *intellectual* faculties—furnished with bodies—with *organs of vision*—locomotive powers. Various other circumstances connected with their existence. Make *progressive* improvement in knowledge. Intercourses among them. Spiritual economy. *Moral state of the inhabitants of other worlds.* Happiness dependent on moral principle and action. Moral order. Moral laws which govern all pure intelligences.. 105

CHAPTER XIX.

A SUMMARY VIEW OF THE UNIVERSE.

Mental process by which we obtain an approximate idea of creation. Magnitude of the earth. Planetary system. Stars visible to the naked eye. Milky Way. Nebulæ—their extent and grandeur. Immensity of creation. Astonishing motions in the universe. Mode by which we may acquire the most comprehensive idea of it. Creation a proof of the Divine Existence. Attributes of Deity. Dependence of all beings upon God. Christian Revelation.......... 113

CHAPTER XX.

ON COMETS.

Description of the parts of a comet. Opinions of Aristotle, Tycho, &c. History of remarkable comets. Comets of 1680, 1682, 1744, 1770. Encke's comet. Biela's and Gambart's. Alarms occasioned by comets. Comet of 1807—Schroeter's and Herschel's observations on—views of this comet. Comet of 1811—Schroeter's observations and deductions respecting its phenomena—destruction of his Observatory. Reappearance of Halley's comet in 1835—observations on, by the Author, Rev. Mr. Webb, and others. Mrs. Somerville's remarks. *Physical constitution of Comets*—opinions respecting their nuclei and tails. *Miscellaneous remarks respecting comets*—their light, phases, and nebulosity—whether they may come in contact with the earth—whether they have ever fallen into the sun. *On the influence of comets on the earth*—opinions prevalent in former times—Forster's hypothesis. Comets *may have* an influence on our globe—its nature not yet determined. Whether the direction of the earth's axis has been altered by a comet. Whether the new planets were disrupted by the shock of a comet, &c. *On the orbits of comets*—their form—how determined. Motions and periods of. *Number* of. Direct and retrograde motions, inclination of orbits, &c. *Inhabitability of comets.* Size and splendor of some comets. Account of Mr. Webb's MS. Treatise on Comets...... 130

APPENDIX.

Aspect of the sidereal heavens for every alternate month of the year, with remarks........... 137
Phenomena and positions of the planets for 1840.................................... 142
Ditto 1841.................................... 145
Eclipses and occultations 1840.................................... 147
Ditto 1841.................................... 147
Occultations of Venus 1841.................................... 148
Explanations of some of the engravings of the stars and planets.................................... 149

THE

SIDEREAL HEAVENS.

INTRODUCTION.

In a work lately published under the title of "Celestial Scenery," I endeavored to exhibit a pretty full display of all the prominent facts connected with the motions, distances, magnitudes, and other phenomena of the planets, both primary and secondary, and of the observations and reasonings by which they are supported. These bodies forming a part of the solar system to which we belong, and lying within the limits of measurable distance, can be more distinctly surveyed, and their magnitudes and other phenomena more accurately investigated, than those of the remoter orbs of the firmament. Hence, in consequence of the accurate observations of modern times, we can now speak with a degree of certainty and precision respecting their order and arrangement, their periodical revolutions, their distances from the sphere we occupy and from the center of the system, their real bulk, the appearance of their surfaces, and the objects which diversify their respective firmaments. But when we pass the boundary of the planetary system, and attempt to explore the orbs which lie beyond it, we have to travel, as it were, through dark and pathless regions, we have to traverse an immense interval which has hitherto baffled all the efforts of human science and ingenuity to determine its extent. The fixed stars lie completely beyond the dominions of the sun; they feel not his attractive influence, they revolve not around him as a center, nor are they enlightened by his effulgence. It follows that our knowledge of those remote luminaries must be extremely imperfect, and our views of the distant regions in which they are placed comparatively limited and obscure.

But notwithstanding the immeasurable distance of the starry regions, and the limited nature of human vision, we are not altogether ignorant of those remote and unexplored dominions of Omnipotence, or of the magnitude and splendor of the bodies they contain. The telescope has enabled us to penetrate the vast spaces of the universe, and has opened a *vista* through which thousands of suns and systems are distinctly beheld, which would otherwise have been forever vailed from the view of mortals. It has extended the boundaries of our vision thousands of times beyond its natural limits, and collected the scattered rays of light from numerous distant orbs, which, without its assistance, would never have entered our eyes. It has served the purpose of a celestial vehicle to carry us toward the heavens, and has produced the same effect on our visual powers as if we had been actually transported thousands of millions of miles nearer the unexplored territories of creation. Guided by this noble instrument, scenes and objects have been disclosed to view of which former generations could form no conception, and which lead the reflecting mind to the most elevated views of the perfections of the Deity, and to the most expansive prospects of the grandeur and magnificence of his empire.
